Robertson et al. 05; Font et al. 05

# LCDM and stellar halos

Hierarchical structure formation leads to idea that stellar halos formed from accreted, disrupted galaxies (~Searle & Zinn).

Stellar halo studies provide means to:

- Measure accretion rates: Stellar streams around galaxies
- Probe Early Star formation: Chemical abundance patterns.
- Test small-scale manifestations of CDM: Substructure counts

# How do dark matter halos grow?

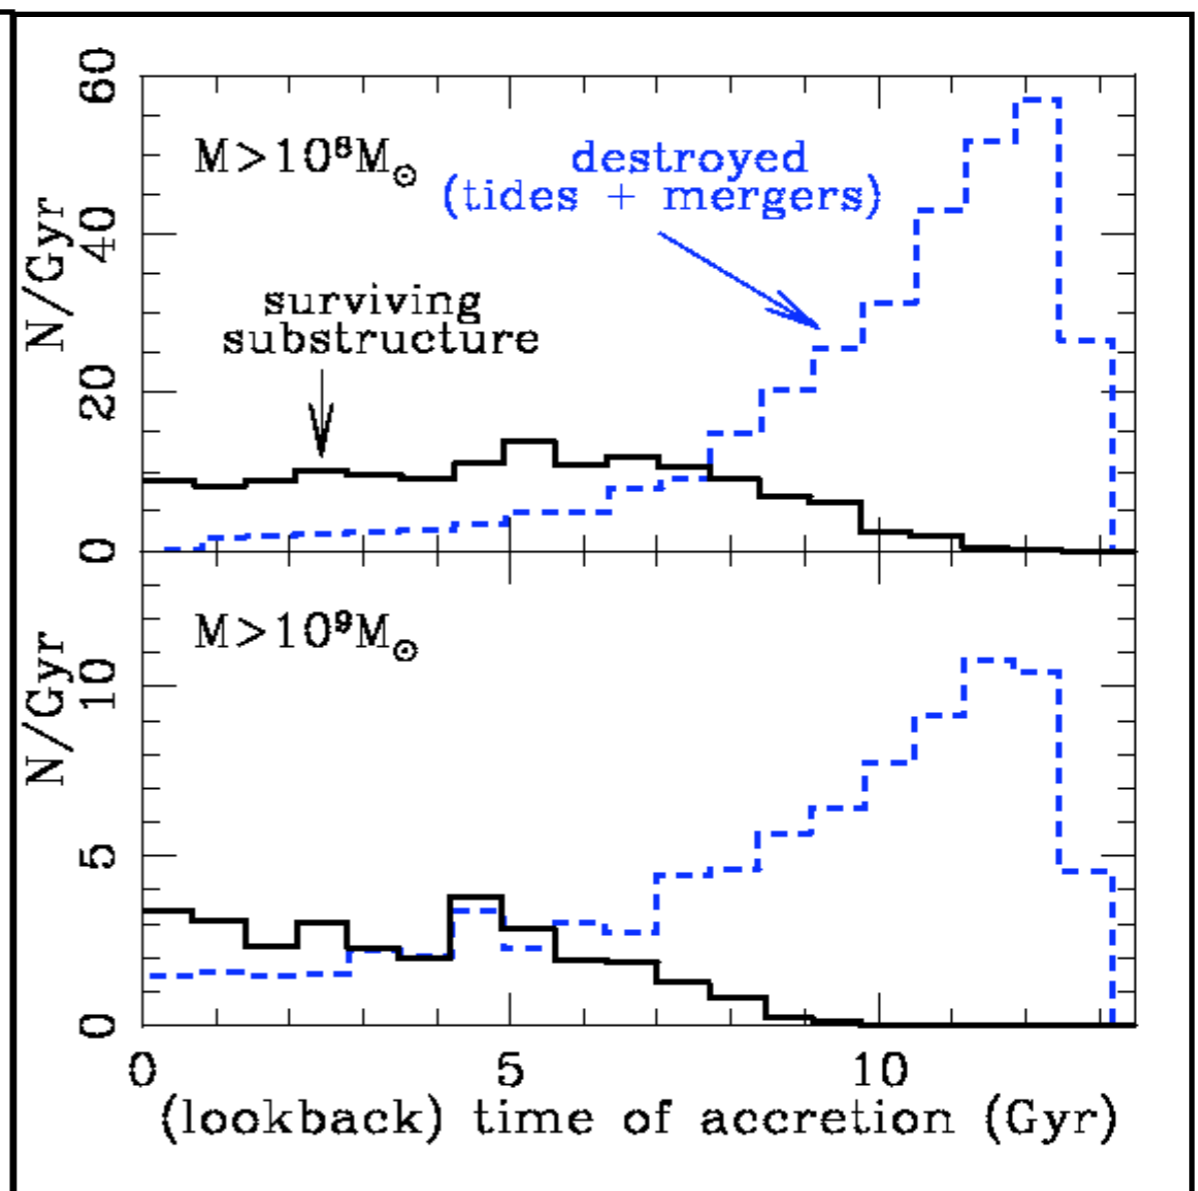

1. Accrete Smaller Systems
2. Destroy them via tides and mergers
3. Repeat

ZENTNER & JSB 03:

**Most accreted subhalos are destroyed.**

Destruction is quicker at early times because halos have higher average densities.

Also Zentner et al. 05

Dark Halo  
Assembly

Stellar Halo  
Assembly

## Galaxy-size Dark Matter Halos: Robust Predictions

1. Most of the mass is accreted in  $\sim 10^{11} M_{\text{sun}}$  subhalos ( $\sim$ LMC).
2. Majority of accreted systems are destroyed before  $z=0$ .
3. Surviving substructure is biased to be late-accreting objects.

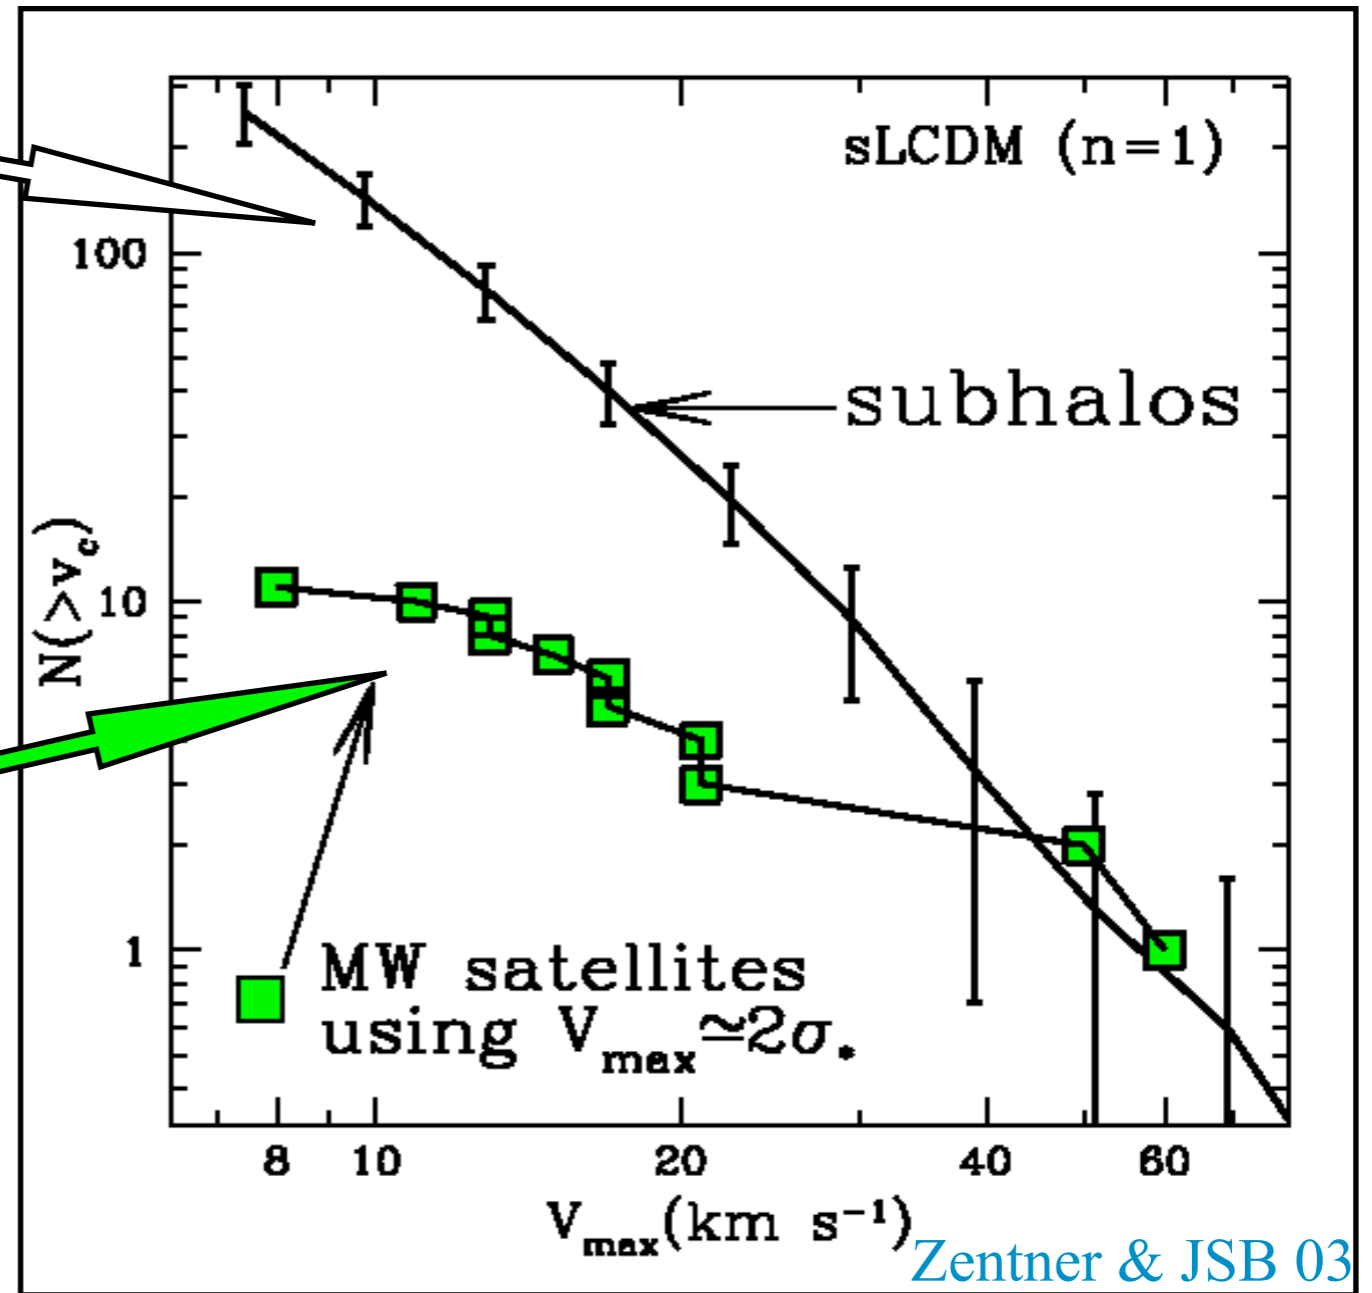

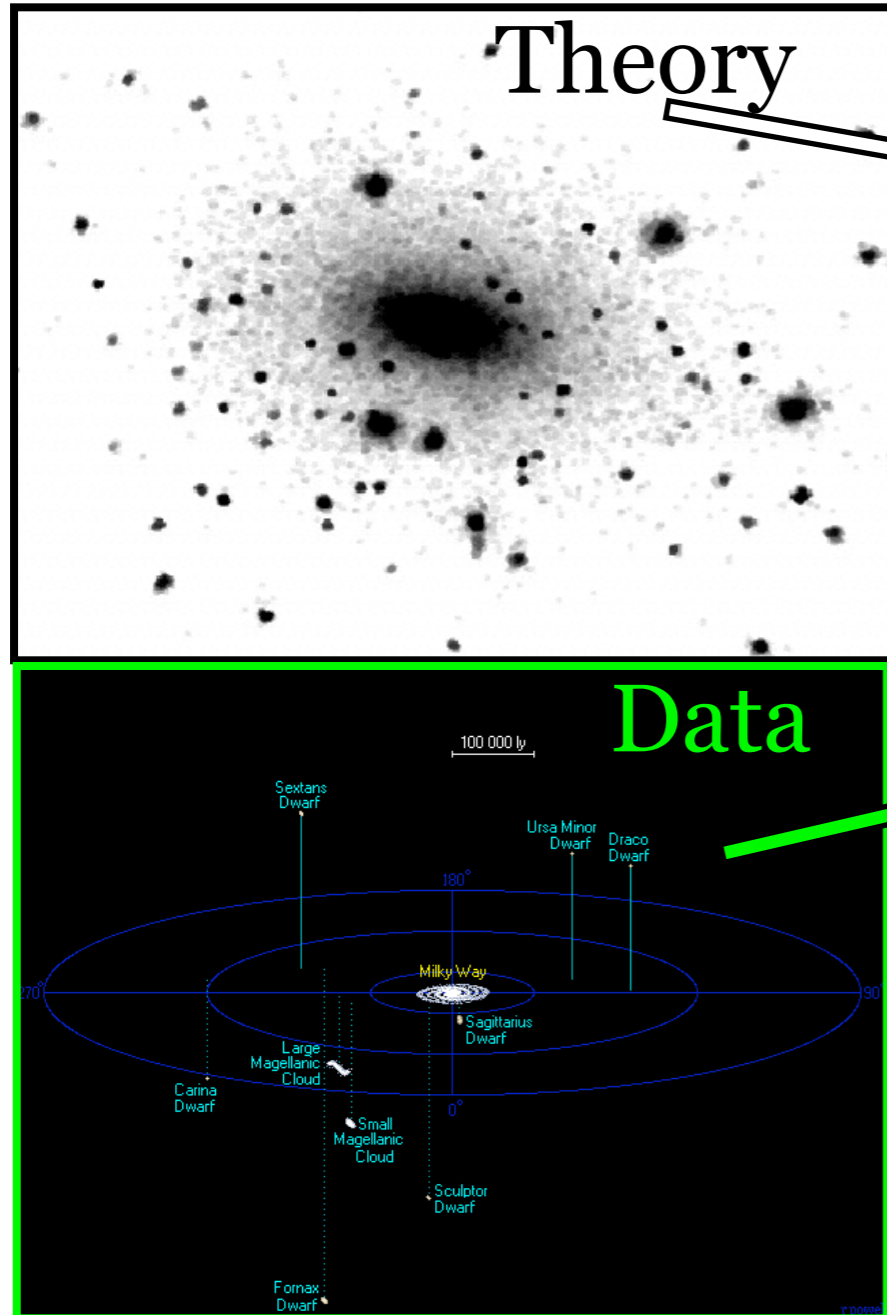

## Stellar Halo Formation: Model Requirements

1. Must reproduce counts and characteristics for local group dwarfs.
2. Must reproduce observed stellar halo mass and density  $\rho(r)$
3. Chemical abundance trends

# The Dwarf Satellite Problem

ΛCDM predicts rising subhalo velocity function. Not observed for satellites of the Milky Way and Local Group:

Klypin et al. 99; Moore et al. 99

# What is the Dwarf Problem telling us?

Something about  
cosmology

**-DARK MATTER NOT COLD?**  
(gravitino = DM?)

Something about  
astrophysics

**-REIONIZATION?**  
**-SUPERNOVA FEEDBACK?**  
(See Gnedin's Talk)

# Stellar Halo Models: Our Method

Fully self-consistent cosmological simulations with the dynamic range needed are effectively impossible.

In order to overcome this difficulty, we adopt a hybrid approach:

1. Use a semi-analytic monte-carlo approach to set star formation histories and dynamic initial conditions.

2. Follow dynamics of merging satellites using a fast expansion-based code with 100,000 particles per accretion event.

# Our Model/Approach:

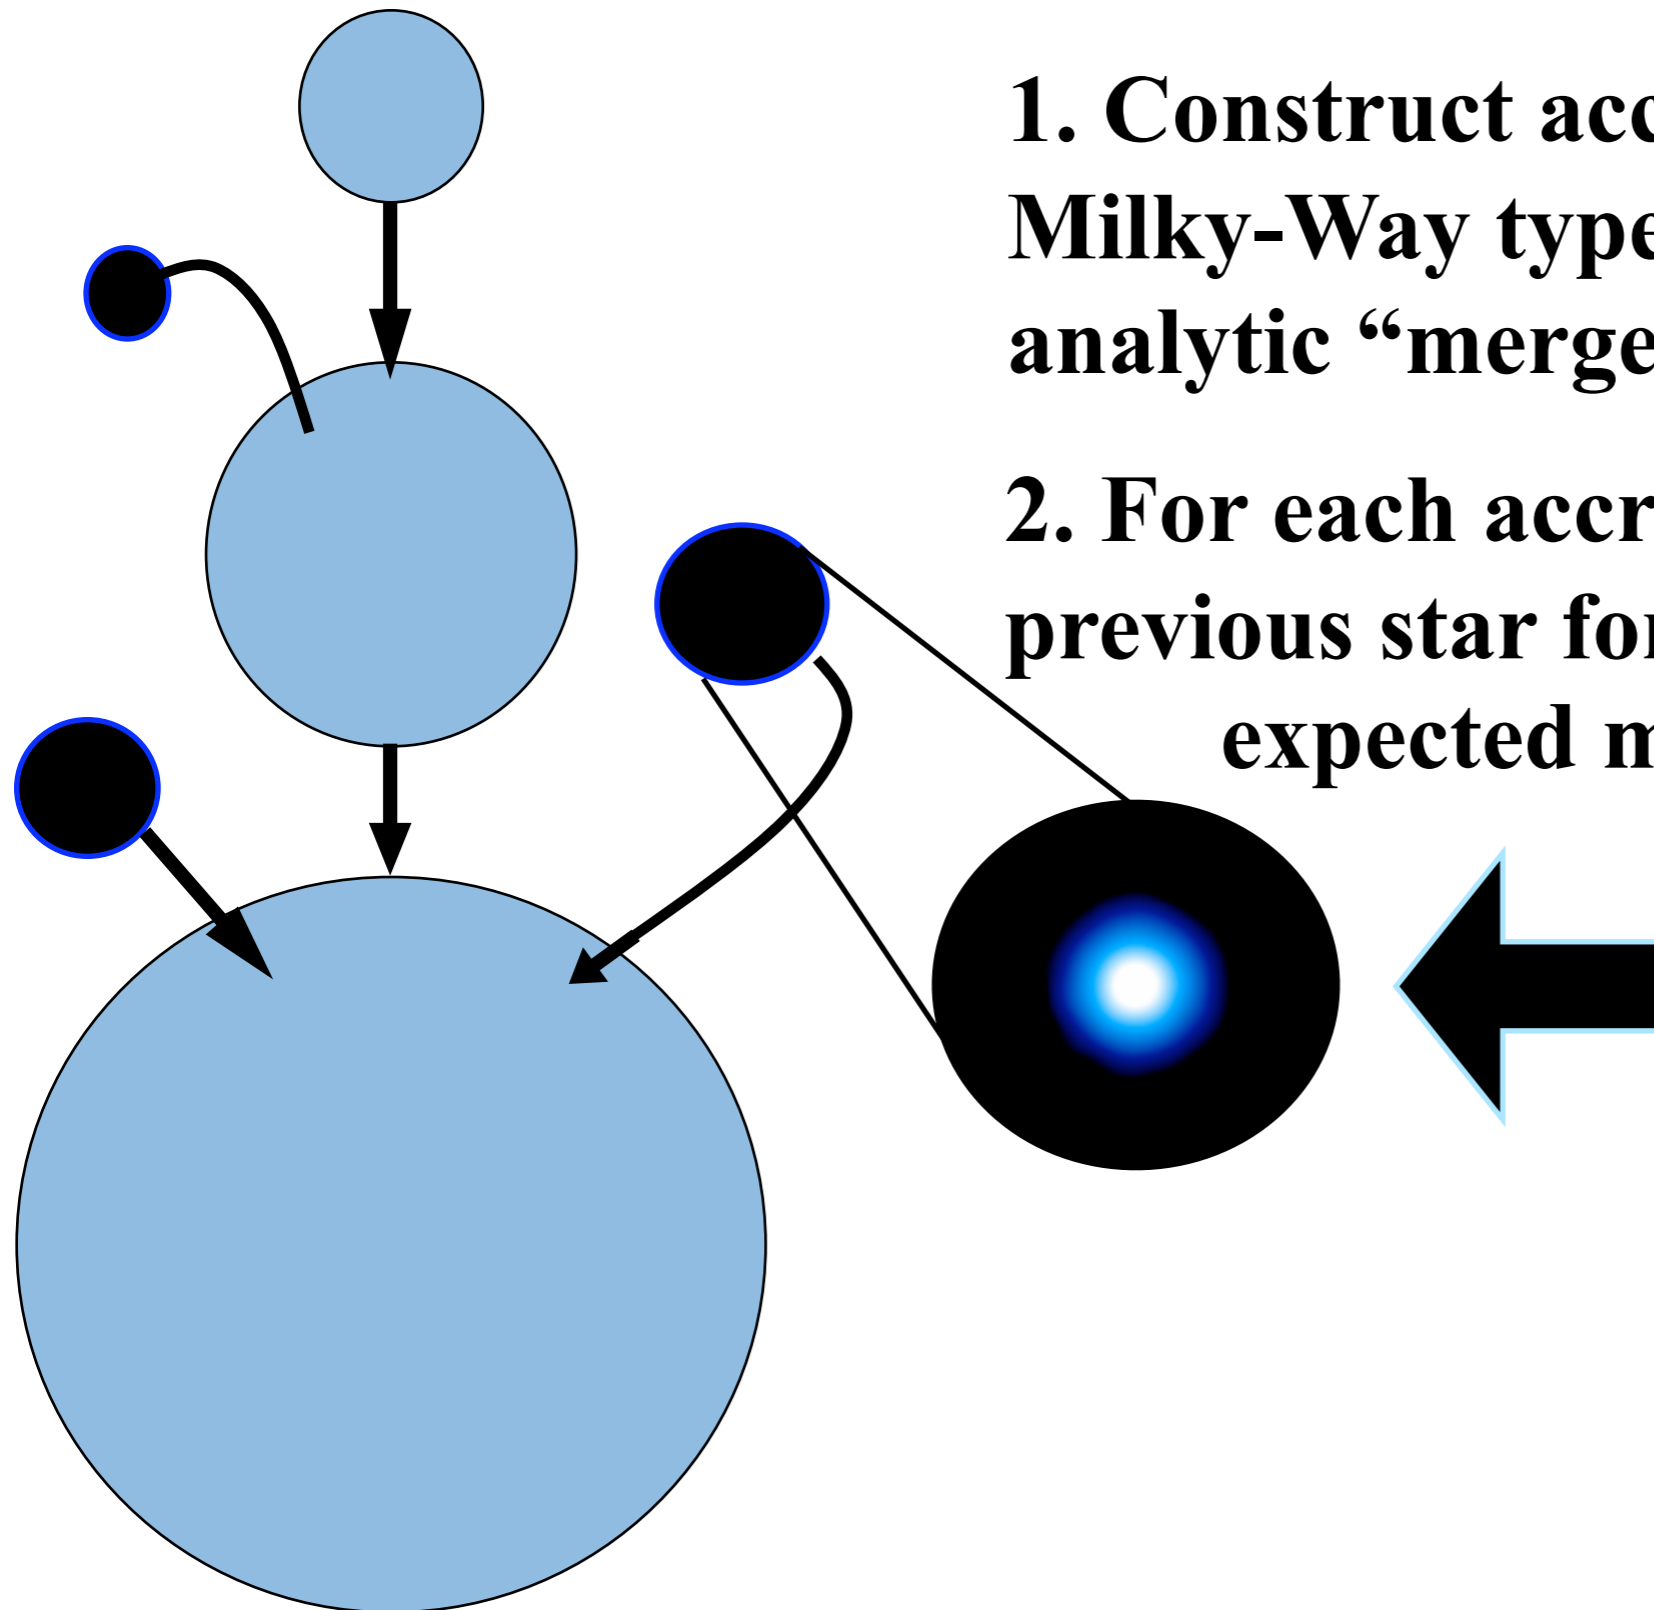

**1. Construct accretion histories for Milky-Way type halos using semi-analytic “merger tree”.**

# Our Model/Approach:

1. Construct accretion histories for Milky-Way type halos using semi-analytic “merger tree”.
2. For each accreted system, model its previous star formation history based on expected mass growth history:

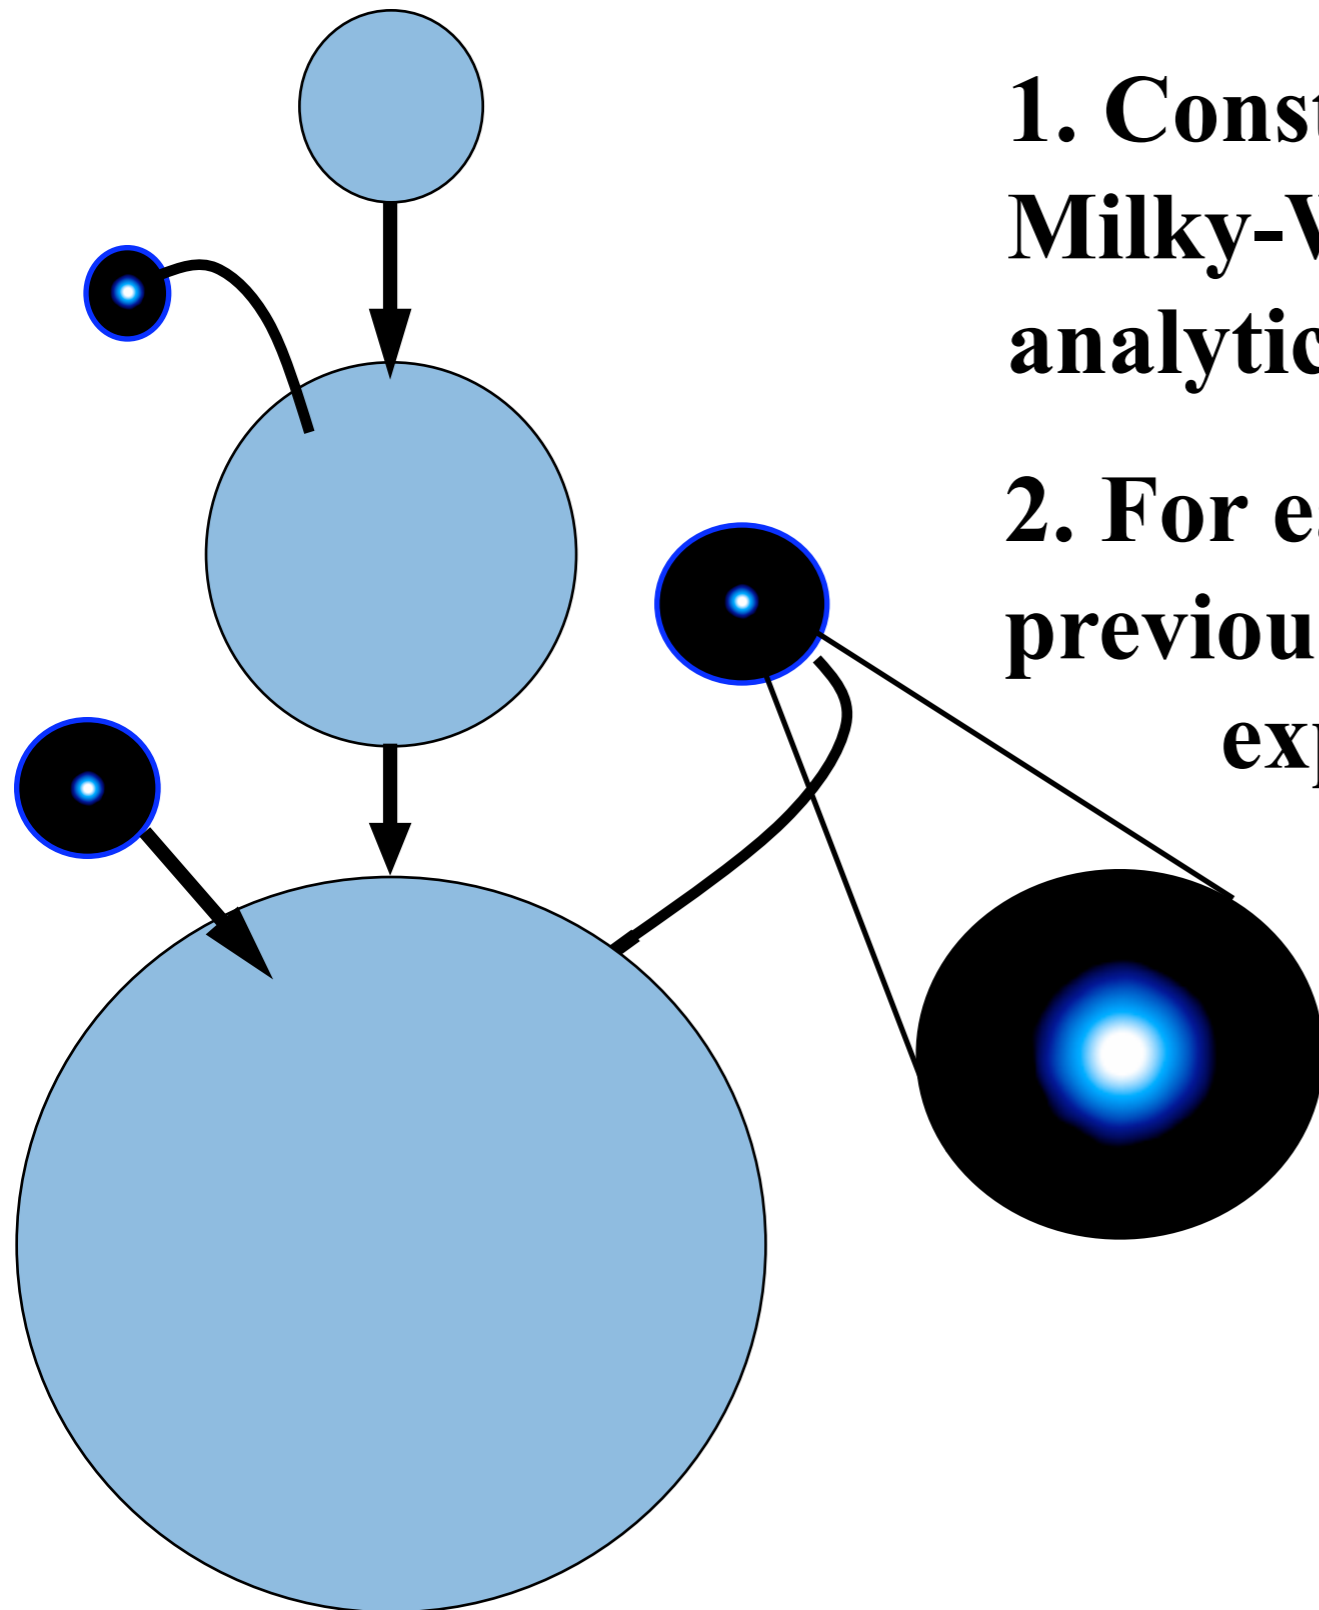

$$\dot{M}_* = \frac{M_{\text{gas}}}{t_*}$$

# Our Model/Approach:

- 1. Construct accretion histories for Milky-Way type halos using semi-analytic “merger tree”.**
- 2. For each accreted system, model its previous star formation history based on expected mass growth history:**

# Our Model/Approach:

- 1. Construct accretion histories for Milky-Way type halos using semi-analytic “merger tree”.**
- 2. For each accreted system, model its previous star formation history based on expected mass growth history:**
- 3. Initialize simulations, embed stellar content into the center of accreted dark matter halo to match a realistic galaxy light profile.**

# Our Model/Approach:

**1. Construct accretion histories for Milky-Way type halos using semi-analytic “merger tree”.**

**2. For each accreted system, model its previous star formation history based on expected mass growth history:**

**3. Embed stellars in the center of accreted dark matter halo.**

**4. Follow evolution within the (growing) host halo using basis function expansion code. 100,000 particles per event.**

# Star formation and feedback in satellites:

Gas / DM mass accretion history:  $M_{\text{DM}} = M_0 e^{-\alpha z}$  ←

N-body simulations  
(Wechsler et. al. 2002)

Star formation law:  $\dot{M}_\star \approx \frac{f_{\text{gas}} M_{\text{DM}}}{t_\star}$  ←

JSB, Kravtsov, & Weinberg (00)

Dwarf halos that formed before reionization retain gas. The rest are dark

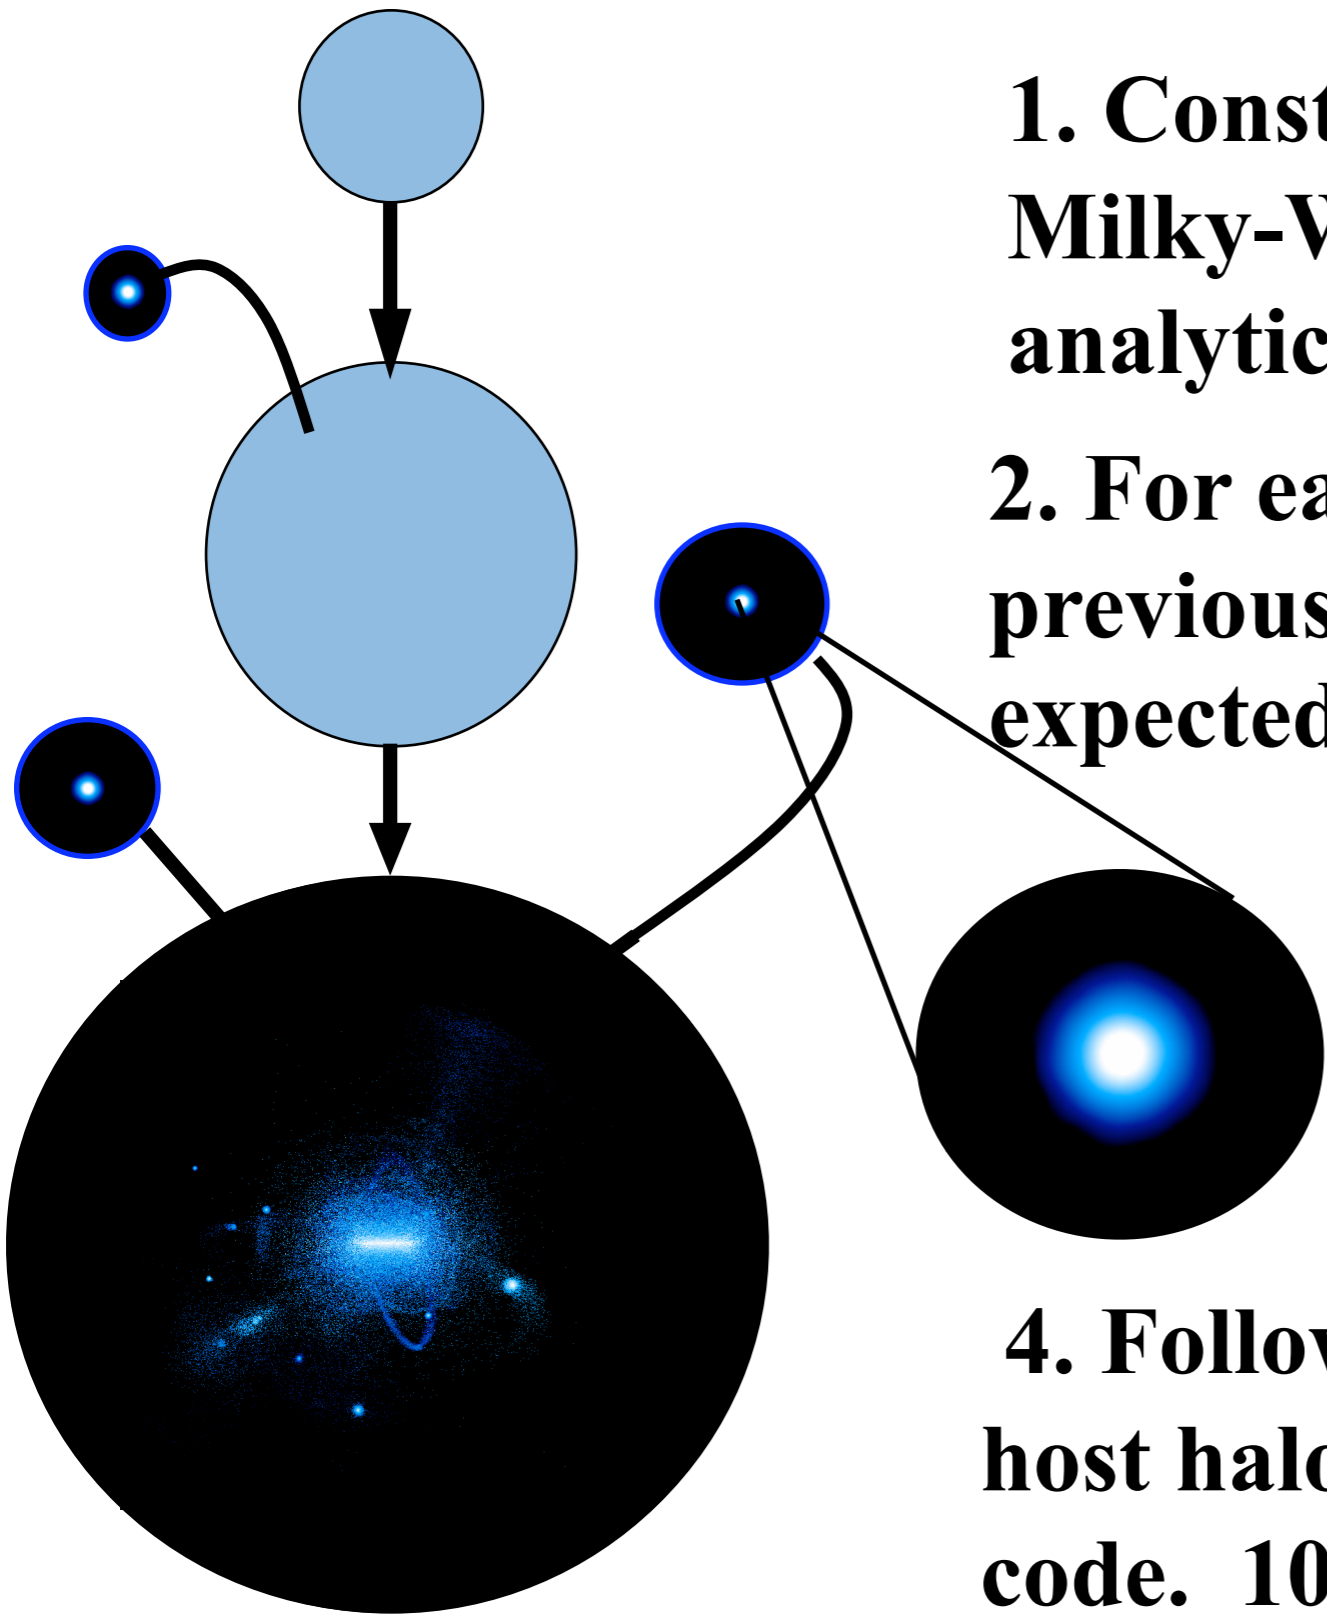

$t^* = 8\text{Gyr}$ :  
Set to match velocity-luminosity relationship for surviving satellites

Blow-out Feedback Law:

$$w \propto V_{\text{max}}^{-2} \leftarrow$$

Set to match metallicity vs. luminosity relation for local group dwarfs

# Our Model/Approach:

**1. Construct accretion histories for Milky-Way type halos using semi-analytic “merger tree”.**

**2. For each accreted system, model its previous star formation history based on expected mass growth history:**

**3. Embed stellars in the center of accreted dark matter halo.**

**4. Follow evolution within the (growing) host halo using basis function expansion code. 100,000 particles per event.**

**End:  $t=0$  (present time)**

**Each point = 1 Tracer Star**

**z=0 Flythrough**

# Gas fractions in accreting dwarfs:

Accreted systems are very gas-rich at early times. This is needed in order keep stellar halo mass near observed level.

Late-accreted dwarfs match typical gas mass fractions seen in \*isolated\* dwarfs.

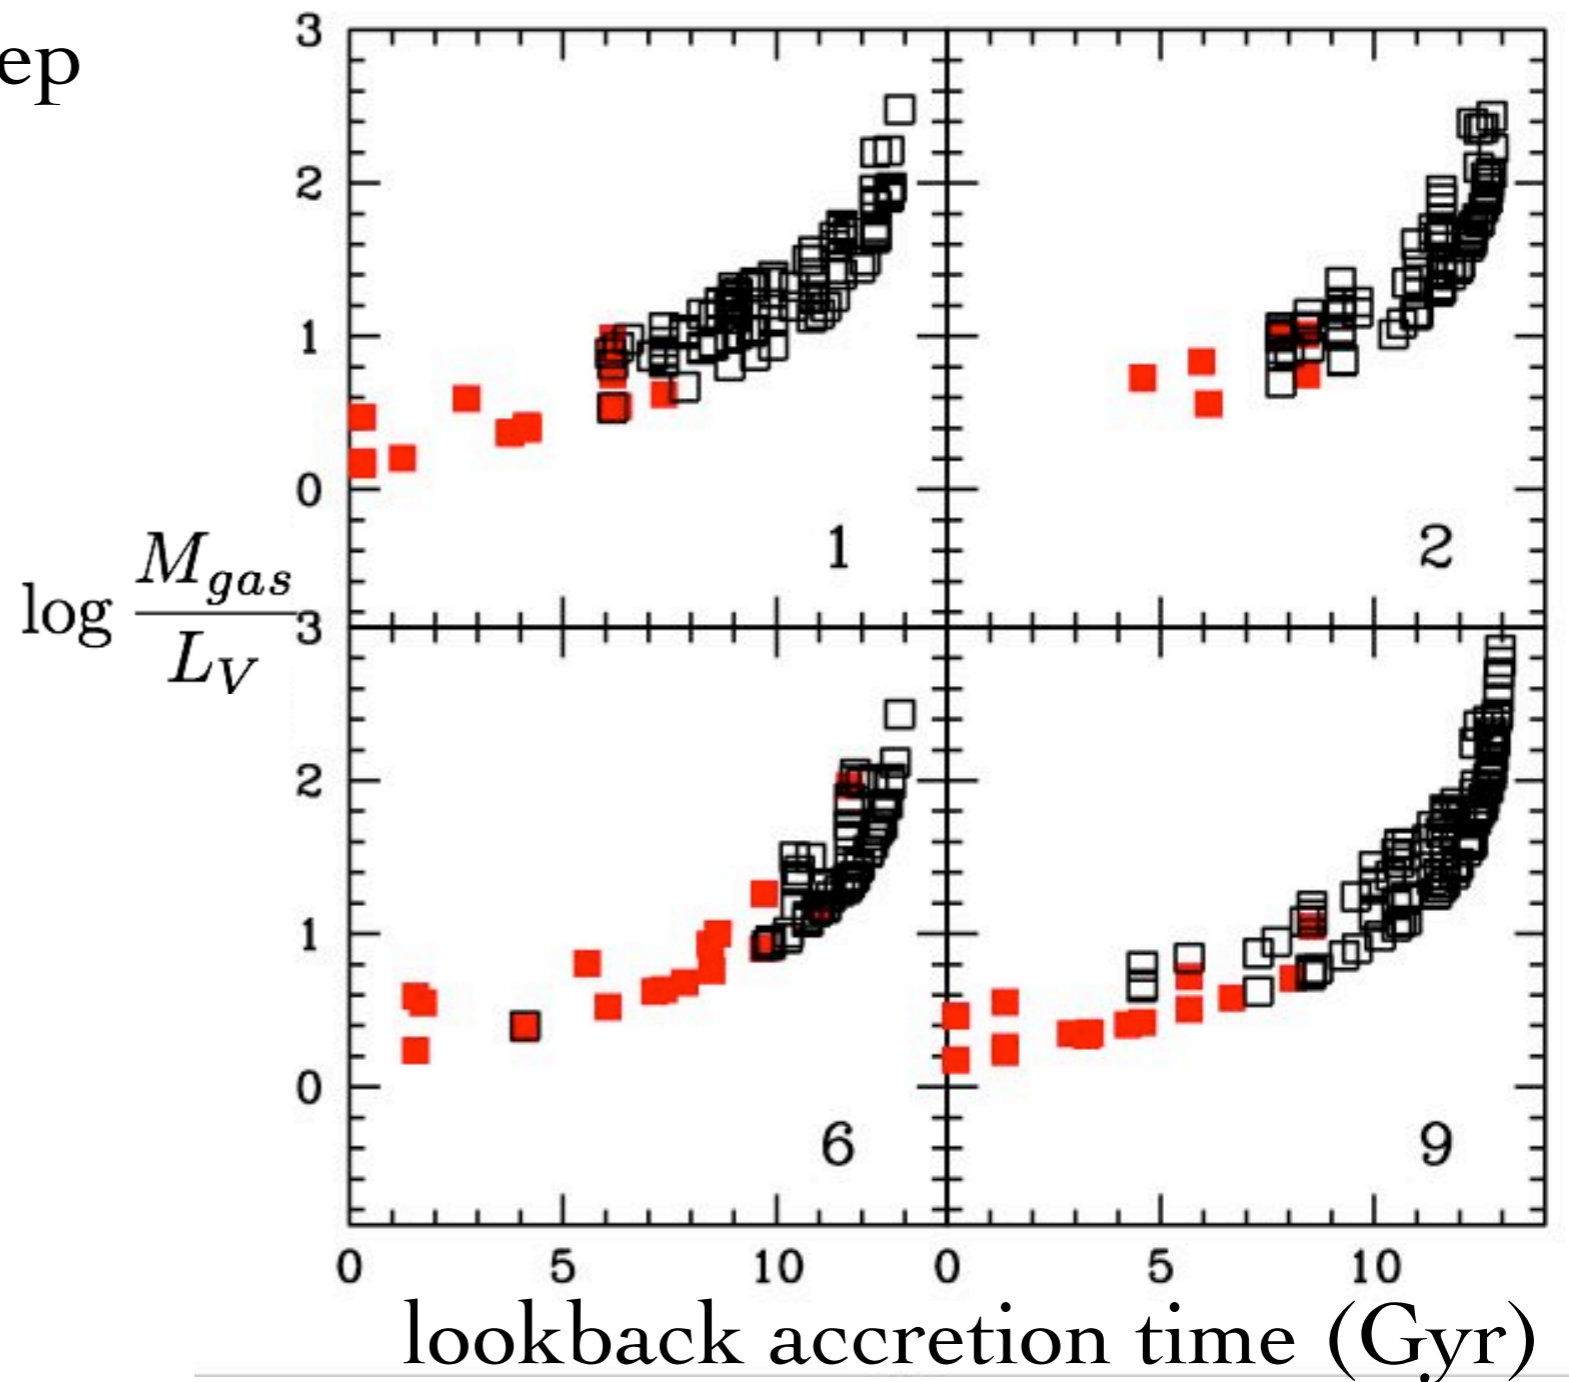

We appeal to ram pressure stripping to explain nearby gas-poor dwarfs:

-- Maller & JSB 04

-- Mayer et al. 05,

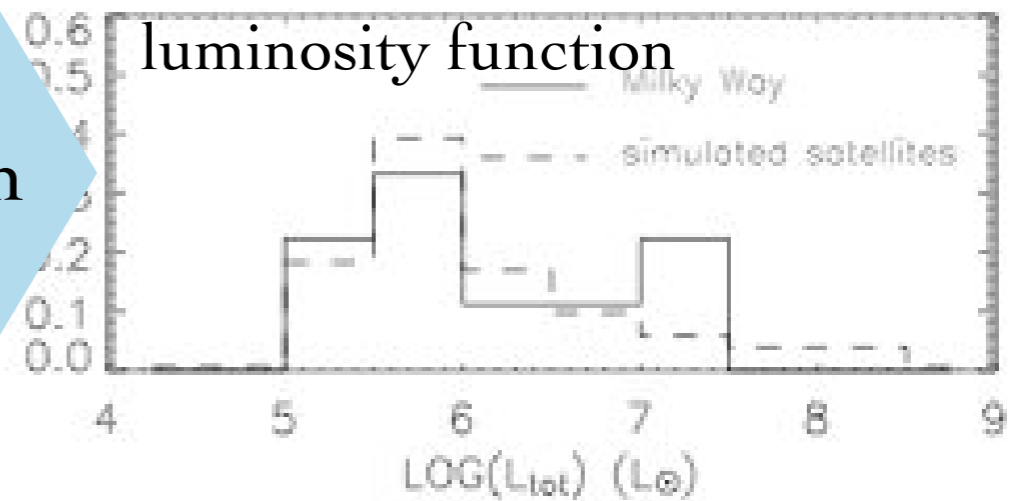

-- Mayer's Talk.

# Alpha abundances...

**Halo:**  
Enhanced alpha  
abundances  
(rapid star  
formation)

**Satellite  
galaxies:**  
intermediate  
alpha  
abundances

Lots of discussion  
in the literature:  
Unavane et al (1996)  
Nissen & Schuster (1997)  
Gilmore & Wyse (1998)  
Shetrone et al. (2001)  
Fulbright (2002)  
Shetrone et al. (2003)  
Tolstoy et al. (2003)  
Venn et a. (2004)

# Solution? Surviving dwarfs are biased.

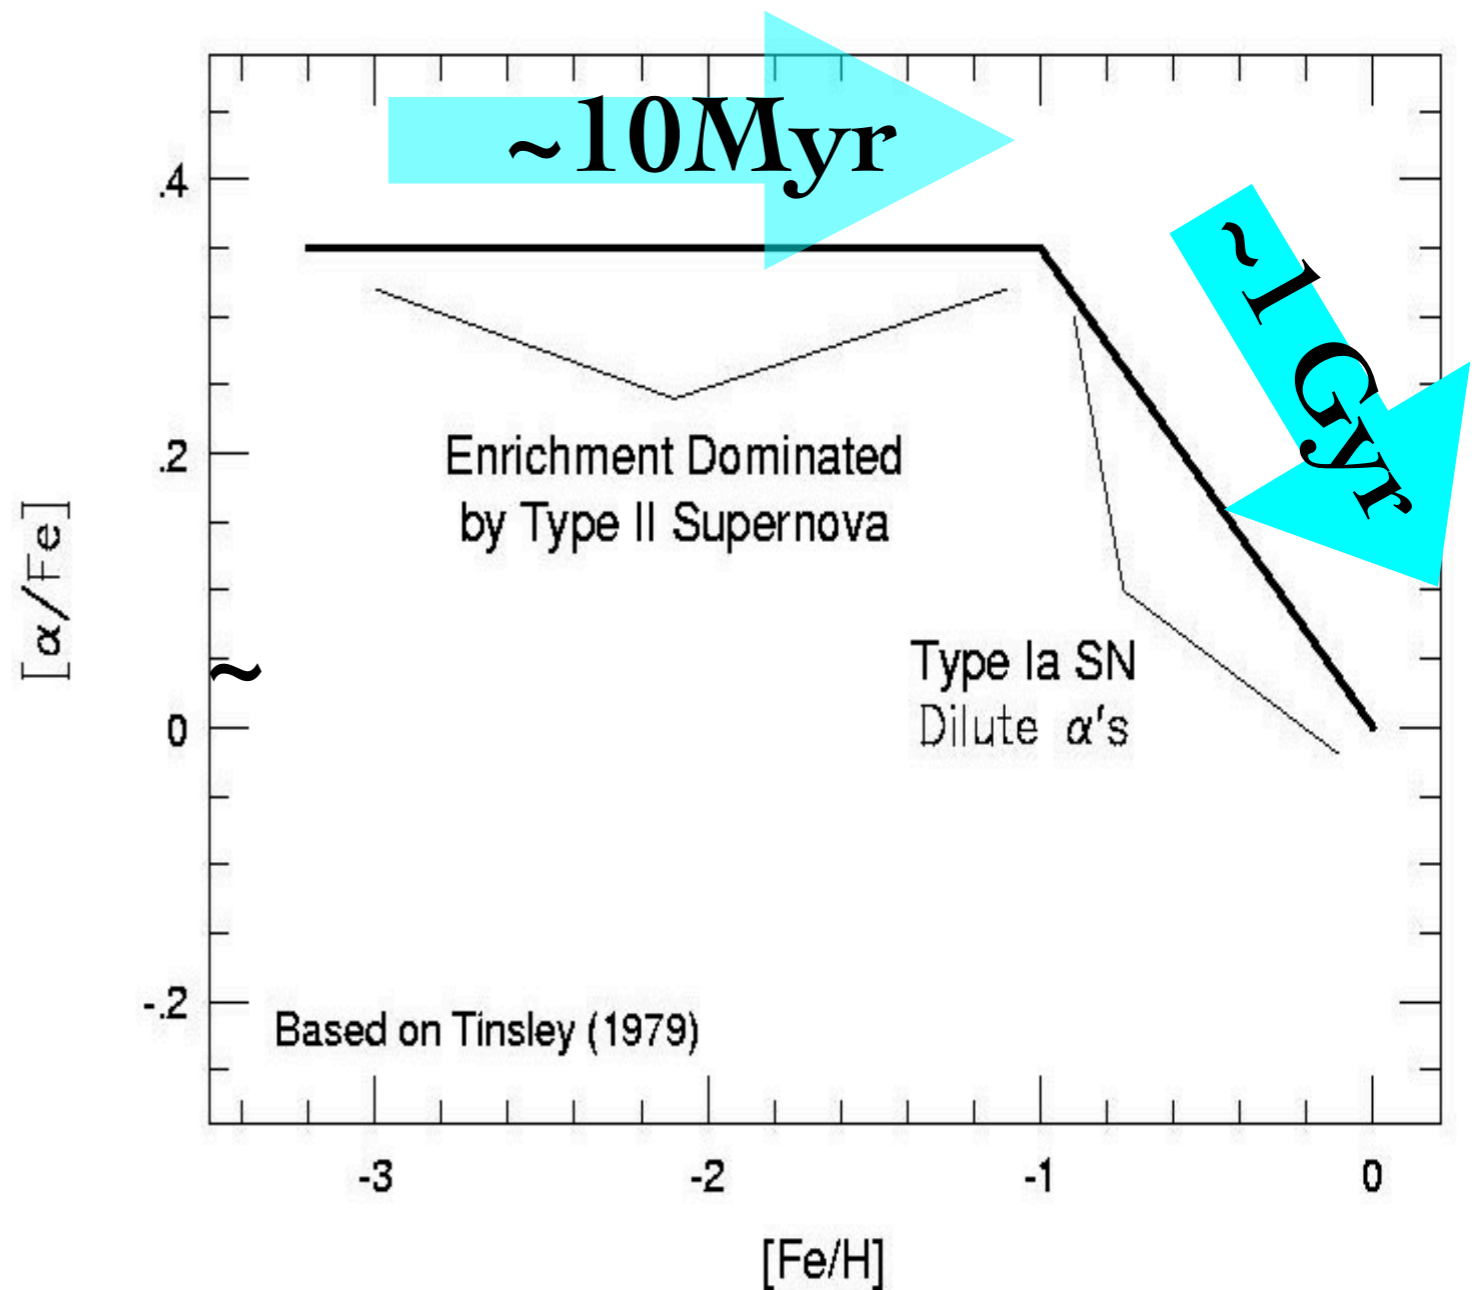

**1. Early accretion events are destroyed.**

**2. Late accretion events survive.**

**3. Most of the \*mass\* is accreted in LMC-size systems.**

# Chemical abundance patterns

- Stars with  $M > 10 M_{\text{sun}}$  explode as Type II supernova within  $\sim 10^7$  yr. Type II SN eject large amounts of “even-Z”  $\alpha$  elements.
- About 1 Gyr later, Type Ia supernova begin to heavily contribute. Mostly eject Fe-group elements. This ‘dilutes’ the  $[\alpha/\text{Fe}]$  value.
- A galaxy’s (or star’s) position on this diagram constrains the type of star formation history it had.

Fulbright

# Chemical Evolution Model: Robertson et al. 05

Start calculation at “z\_re=10” with  $[Fe/H]=-4$ , with a Kroupa “Pop II” IMF.

SNI & SNI rates and yields

(Greggio & Renzini 1983, Thielemann et. al. 1996, Nomoto et. al. 1997)

Stellar wind enrichment

(van den Hoek & Groenewegen 1997)

# Font et al. 05

Chemical evolution  
models + N-body  
simulations

Halo is alpha-enhanced  
because it is  
formed from  
earlier accretion  
events. Surviving  
satellites were  
accreted later.

# Conclusions

- Models for the stellar halo based within the LCDM context can reproduce the gross characteristics of the stellar halo and local group satellites.
- Chemical Abundance Pattern seems to arise naturally in this context.

● Surveys are underway to test whether the stellar halos of the Milky Way and other nearby galaxies look like this... test whether structure formation is indeed hierarchical on small scales.

# Maller & JSB 04

Thermal instability &  
fragmented Cooling

Helps “overcooling” in  
massive galaxies.

Residual, low density  
 $10^6\text{K}$  galactic corona,  
important for ram pressure  
stripping.

# Metallicity Gradient: Outer Regions more metal rich
