MEASURES OF PROGRAM EFFECTIVENESS

There are two distinct strategies for measuring the sanitation and replanting effectiveness of local shade tree programs: rely on the descriptions of program activities (provided to the state at the end of each calendar year) or utilize the judgments of experts (the state shade tree program inspectors). Both have been utilized in this analysis; procedures used to develop these measures and their interrelation are described below.

I. Inspector's Judgments

The six inspectors associated with the state shade tree program were asked to complete a questionnaire that involved rating the 507 local programs (supervised and receiving financial support from the state program) on four characteristics: overall program effectiveness, sanitation effectiveness, replanting effectiveness, and commitment to urban forests. An example of the rating form is provided in Exhibit A-1; note that all programs were rated on one aspect (e.g. overall effectiveness) before receiving evaluations on the next. For each program, an inspector indicated whether he thought the program was excellent, excellent to typical, typical, typical to very poor, or very poor; a 5.4 interval scale. In addition, they could indicate an unwillingness to rate a program (for any) reason) and were asked to provide their confidence in their judgment — high, medium, or low. For the analysis, an excellent rating was assigned a value of 1, very poor a value of 5, and intermediate responses the values of 2, 3, and 4.

EXHIBIT A-1.

REPLANTING PROGRAM EVALUATION

For each of the following communities or counties, please indicate your rating of <u>ONLY</u> the replanting program and your confidence in each rating. If you cannot rate a program for any reason, please check the column to the far left.

In order to estimate the reliability of the ratings, a comparison was made of the ratings of the same local programs by all combinations of two inspectors. The results for judged effectiveness of sanitation and replanting is presented in Exhibit A-2. In some cases two inspectors (A and D, A and E) simultaneously rated only 1 or 2 programs and no correlation coefficients could be computed; in other cases as many as 193 programs were rated by two inspectors (A and E). The average correlations between inspectors ranged from 0.49 to 0.58; high enough to indicate some agreement on what constitutes a good program but low enough to suggest that not all inspectors view programs in the same way. Though sufficient, reliability might be improved if more effort had been devoted to development of the ratings scales.

Letters identify the six state program inspectors.

Agreement Among Inspectors on the Evaluations of Program Effectiveness

To develop measures of program effectiveness, each local program was assigned a value that was the average of all inspector ratings where provided by one, two, or more inspectors. From 14-67 of the local programs were not rated by any of the state program inspectors. The distribution of average evaluations of all programs is provided in Exhibit A-3.

II. Program Activities

The alternative measures of program success are related to the actual activities pursued in the program, minimizing the spread of the Dutch elm disease and replanting shade trees to replace those lost to the disease. The basis for this information was the reports filed by the various programs at the completion of each calender year, reports required before the financial support from the state can be provided. These reports were available for 1977, 1978, and 1979, corresponding to the three years the state program has been in operation; some local programs have been in operation considerably longer. The primary measure of sanitation success was the numbers of trees infected with the DED in a given year, indicated by either those marked (identified as diseased) or those removed (after being marked). To some extent these two measures are redundant, for the correlation between the numbers of trees marked and removed is extremely high (0.99 in 1979); 94 percent of the average number of marked trees were removed in 1979.

As the annual loss of elms as a percentage of pre-disease season inventory has been widely used as a measure of sanitation performance (Cannon and Worley, 1976), it was adopted for this project in two forms, percentage of 1979 inventory marked as infected and percentage of 1979 inventory removed as infected. The most current data, for 1979, were chosen as most likely to be related to the evaluations of inspectors. However, as a

measure of typical performance, compensating for the possibility that 1979 could have been an unusual year, the average percentage of inventory removed over the three year period for which data was available (1977, 1978, and 1979) were also chosen. Thus three quantitative measures of sanitation success were computed and used in this study.

While the attempts to control the spread of Dutch elm disease must be continuous and systematic to be effective; replanting programs may be developed at a more leisurely pace. A community may forego replanting during a given year in order to plan the restocking of the urban forest or implement a large scale replanting; one that could be more economical to implement than individualized tree replacement. Hence, two measures of program activity were chosen to represent replacement success, total trees replanted as a percentage of trees removed over the same three years and total trees replanted as a percentage of the beginning inventory of public elms (in 1977).

The distribution of the communities on the five measures of program activity, three related to sanitation effectiveness and two related to replanting effectiveness, are presented in Exhibit A-4. Note that except for the average percentage of beginning inventory removed over the three past years, all of the distributions are quite skewed toward zero. On the other hand, there is a substantial range of values which will facilitate most analyses.

Exhibit A - 4 Distribution of Measures of Program Effectiveness

III. Comparison of Measures

A major issue for any research is determining the extent to which measures of the same thing (program performance) are in agreement. The correlation between the inspectors' evaluations and the measures based on program activities is presented at the bottom of Exhibit A-5. Note that while the inspectors' evaluations show some internal consistency (a correlation of 0.36 between sanitation and replanting); there is little or no correspondence between the inspectors' evaluations and measures of program impact, none is as high as 0.10. This is further demonstrated in Exhibit A-6, which indicates the low correlations among the measures chosen for the analyses in the main report (Chapters IV and V).

This great discrepancy between the inspectors ratings and the measures of program impact suggests that they reflect two distinctly different aspects of the community programs. It should be observed that the worst possible alternative — strong negative correlations between the two types of measures — has not occurred. If it had, attempting to select appropriate measures of performance would have been substantially more difficult. Both sets of measures have been given attention in the analyses of program impact.

APPENDIX B

CITIZEN INTERVIEWS

In order to determine the possible importance of the behaviors, perceptions, and attitudes of typical community citizens regarding shade trees and the local shade tree program, a survey was completed of residents of selected communities (all with populations of at least 200); this appendix describes the conduct of that survey. It reviews a number of activities related to that goal, constraints on the sample of communities and individuals, a description of the selection of communities chosen as representative of two regions, selection of dwellings within each community, selection of respondents within each dwelling, and conduct of the telephone interview itself.

It was impossible to expect to develop descriptions of citizens in over 500 communities with shade tree programs; time and budget constraints would allow for no more than several thousand interviews. It was determined that fifty interviews in each of forty communities was the optimal mix between scope and precision (details for each community). Eventually, the interview quota was reduced to 25 for communities with populations less than 2,000 and only 36 communities met the criteria chosen for selection without excessive redundancy. Further, a sample representative of two regions of the state was desired (south central and northwest), requiring a system of selecting respondents representative of urban residents within a region. These procedures are all described below.

At the completion of the citizen survey, data on attempts to reach individual respondents were available on 54 communities representing 96.5

percent of all completed interviews (omitting 15 communities in which 3.5 percent of the interviews were completed). In order to obtain 1,608 interviews it was necessary to call 4,048 phone numbers; of these, 1,722 (or 42.5 percent) were not eligible for an interview (16.5 percent were not working phones; 17.9 percent were not located in the appropriate community, or were farms or rural residences; 4.7 percent were not residences of any kind; 3.4 percent involved other problems). Of those 57.4 percent eligible for an interview, interviews were actually completed with 69.1 percent. While complete data is not available, it would appear that approximately half of those refusing to provide an interview were either not interested in being interviewed on any topic, suspicious and concerned, or resented the request for a specific person from the household (part of the interview procedure discussed below). The remainder were evenly divided among those that either had no elms or their property or no responsibility for any trees (frequently those living in apartments), were specifically not interested in trees, genuinely too busy for the interviews, or reflected a number of miscellaneous complications (hearing problems of the elderly, sick or ill, poor command of English, and so forth).

I. Selection of Focal Communities

The forty communities to be selected for citizen interviews, where the results were to be considered typical of their residents, were to be considered most useful for the research if several criteria were met:

1) Participation in the state shade tree program occurred for 1979 and 1980.

- 2) A range of success in sanitation and replanting program
 effectiveness was represented; this was based solely on the
 state inspectors judgments for community selection.
- 3) A range of sizes, as determined by the 1970 Census should be included.
- 4) As much as possible, all regions of the state should be represented: north, central, south, and metro.

All communities in the state were classified in terms of these four characteristics. In those cases where more than one community met all the desired criteria, a random number table was used to select the quota of communities, usually for medium to small communities with moderately successful programs. Because communities did not exist for all possible categories (at least 15 distinct types), only 36 cities were eventually chosen for the citizen surveys. They are presented in Exhibit B-1, two-digit numbers following the name of the community indicate the number of completed interviews.

EXHIBIT B-1: SELECTION OF CITIES FOR COMMUNITY SURVEYS AND CASE STUDIES (Paul D. Reynolds, 17 July 1980)

^{*} Indicates selection for a case study.

II. Regional Samples of Communities

Selection of respondents in two state regions to represent those citizens of urban communities (over 200 residents) that may qualify for or have a shade tree program is a multi-stage process, involving selection of communities, dwellings, and respondents. The procedure is designed so that the communities to be chosen for the sample are selected proportionate to their size. (Sudman, 1976, Chapter 7). The cluster size was chosen as five, found to be optimal for research on attitudes and perspectives (Sudman, 1976, p.81). As 50 interviews were allocated to each region, this resulted in 10 clusters per region. A procedure was developed such that if a given city was a "certainty sampled size" (that is more than 10 percent of all residents of communities over 200 lived in that city), it did not complicate the selection of other communities that had less than 10 percent of eligible urban residents (that is, the remainder continued to be selected proportionate to their size).

The specific procedure used in the selection of these regional communities is presented below:

- 1) The total urban population of the region was computed by summing the 1977 population for all individuals in cities over 200, excluding townships.
- 2) The total urban population figure was then divided by the number of five-interview clusters; ten were selected for each region.

 This yielded the "certainty sampled" city size; 10 percent of the total "urban" population.

- 3) Any city (or cities) larger than the certainty sampled size was selected and the population of these subtracted from the total "urban" population for the region. The number of clusters needed was then reduced by the number of certainty sampled cities.
- 4) A new certainty sample size figure was calculated using adjusted population and cluster figures.
- 5) Any cities larger than the new certain sample figure were selected and appropriate adjustment made to urban population figures and the number of desired clusters.
- The aforementioned procedure was repeated until there were no cities larger than the final certainty sampled size remaining. This figure was then used as the sampling interval to obtain the remaining cities required. As the cities were listed alphabetically, this should not lead to any systematic bias.

Cities selected by the certainty sample interval were occasionally much larger than that interval and, consequently, were allotted more than one cluster of five interviews. This would result in fewer than 10 cities chosen for that particular region.

The following cities were selected to represent two regions by this process (those indicated with an asterisk (*) were also chosen as focal cities, discussed above, quota of interviews indicated in parentheses):

South Central Region: Dundas (5), Dunnell (5), Good Thunder (5), Hayward (5), Mankato (5), New Ulm* (5), Medford (5),
Nerstrand (5), Nicollet (5), Winnebago* (5).

Northwest Region: Climax (5), Crookston (5), Gonvick (5), Greenbush
(5), Lake Park (5), Moorhead* (15), St. Hillaire

(5), Stephen (5).

Once these cities were selected as units of analysis for their programs, the sampling procedure moved into its second stage whereby the sampling units (residential phone numbers) were selected.

III. Sampling Within Communities

Once communities were selected for citizen interviews, the next stage of the procedure was to select phone numbers for interviewers to call (to be followed by a procedure for selecting a respondent from a household). This involved identifying those phone exchanges and/or phone numbers associated with a given community and selecting an appropriate number to be called on a random basis. Simply generating lists of random numbers (as for exchanges where the first three or four digits were known from state public utility commission data) was not feasible because of the large number of unused banks (last three digits) in small communities. National surveys have found that 80 percent of randomly dialed phone numbers are not connected to residential phones (Cooper, 1964). Consequently, other procedures for developing lists of suitable phone numbers were used.

The initial procedure involved sampling directories from the chosen communities to determine which were the working banks of phone numbers (originally developed by Sudman, 1973). The procedure is self-weighting

in that each bank of phones is given a weight appropriate to the percentage of phones in use in the survey of phone numbers. Once the working banks have been identified, the procedure involves the use of a random number table to generate the last three digits in the seven digit phone number.

This procedure was initially used to generate phone numbers for communities with substantial populations (several thousand or more). In some cases, the directory for communities included the phone numbers of adjacent small communities and resulted in the inclusion of unwanted phone numbers. This led to inquiries of the local phone companies and, contrary to the experiences of other investigators attempting such inquiries in metropolitan areas, the desired information on service areas associated with different phone banks was invariably provided.

However, this method still produced a large percentage of inappropriate phone numbers (no working instrument). Consequently, it was abandoned in favor of an equally effective and less time consuming procedure that involved systematic directory sampling and adding 10 to each phone number selected; ensuring that the instrument was selected at random, that unlisted numbers were not excluded, and the respondents identity would remain unknown.

The systematic directory sampling method used was as follows:

- All appropriate directors for the communities selected were obtained.
- 2) All pages with phone numbers were totaled.
- 3) All phone numbers on a sample of pages (5-20) were counted (more pages for larger directories) to estimate the number of listings per page.

- 4) This figure was used to estimate the total listings for the directory.
- Total listings were divided by the number of listings necessary to obtain the interviews scheduled for that community (oversampling allowed for refusals, non-working phones, non-residence phones, etc.).
- 6) This figure constitutes the sampling interval for the community, used in one of several ways to select phone numbers;
 - a) <u>Directory Sampled</u>: After a random start, the sampling interval was used to select specific numbers for small cities or those in the metro region where exchanges were not bounded by city limits.
 - b) Modified Random Digit I: Working banks representing
 the first four digits were estimated by directory sampling and the last three digits were selected at random.
 - c) Modified Random Digit II: Specific phone numbers were selected from the directory, after a random start and using the sampling interval, and 10 was added to each one, to ensure anonymity of respondent and inclusion of unlisted phone numbers.

The only major variation from discrete counts involved using rulers to estimate the number of listings per inch; substantially reducing the time required to obtain estimated counts of listings.

The different procedures were used in the different cities as follows:

Directory Sampled (due to small size or no discrete exchange)

Large Focal Communities: Bloomington, Coon Rapids, Golden Valley,

St. Paul.

Medium Focal Communities: Dayton, Eden Prairie, Lauderdale, St.

Paul Park.

Small Focal Communities: Avon, Birchwood, Buhl, Brownton, Ham-

burg, Hanley Falls, Lafayette, Lakefield,

Lamberton, Mountain Lake, North Branch.

South Central Regional: Dundas, Dunnell, Good Thunder, Hayward,

Medford, Nerstrand, Nicollet.

Northwest Regional: Climax, Greenbush, Gonvick, Lake Park,

St. Hillaire, Stephen.

Modified Random Digit I & II

Large Focal Cities: Albert Lea, Duluth, Moorhead, New Ulm,

St. Cloud, Stillwater.

Medium Focal Cities: Aitkin, Aurora, Granite Falls, Jackson,

International Falls, Milaca, Winnebago,

Morris, Spring Valley, Wells, Worthing-

ton.

South Central Region: Mankato.

Northwest Region: Crookston.

Because of the efficiency and suitability of the modified random digit procedure II, it was used for the resampling of all cities where this was necessary, whether the initial sample was selected by directory sampling or modified random digit procedure I. There is no evidence to suggest that any systematic bias affected the selection of the phone numbers provided to the interviewers; the inability to utilize forty percent of the chosen phone numbers would suggest that all procedures approximated a random selection.

The final result of this process was a list of phone numbers, provided for each community, entered on the attached form (Exhibit B-2). The interviewers then took these numbers and called them to select a respondent for the interview (discussed in the next section). As there was no way of knowing what response will occur when a random phone number is dialed, several alternatives must be ruled out before an adult member of a residence is chosen for an interview. Specifically, those phones not located in any residence (usually commercial establishments) and those in residences outside the community are excluded after the appropriate questions. Most small towns have one exchange that covers all the surrounding area, including farms and rural residences, so this is a major issue in restricting interviews to households within the community. For each phone number, interviewers attempted to reach a person three times on three different days and, as much as possible, different times of the day. If there was no answer after these three attempts it was not considered a "rejection," but placed in the other category. Instructions for the interviewers for the use of the phone list sheets is presented in Exhibit B-3.

INTERVIEWERS GUIDE

Phone Number Lists

Attempt only the number of interviews required for a community in one evening. Multiple attempts to complete a call which initially resulted in a <u>busy signal</u> may be made in one evening. However, the data and time should not be entered on the phone list more than once per data.

Not in city, not a residence and refusals are not to be considered as a call or attempted call. Therefore, continue on the same phone number list until the required number of interviews or attempts are achieved.

Respondent not in section should be marked and the time, data, and desired person's first name written in the notes section if that is the case or if the person has requested that they be interviewed at a later time or Both of these situations are considered as call backs since the number is valid (appropriate) for the survey but an interview could not be completed at that time. Call back questionnaires and the phone number list from which the number was found should be placed in the call back If the phone number list also contains "incomplete" (e.g. attempts which resulted in no answer or busy signal) the call back box takes priority over the incomplete box for placement of the phone number list. This is because with a "call back" we have a set time to make a return call whereas an "incomplete" number can be tried at any time. If a "call back" results in a successful interview and the phone list contains incomplete calls, either attempt to complete those calls or return the phone number list to the incomplete box.

Exhibit B-3 (1 of 2)

The incomplete box contains those phone number lists and the corresponding questionnaires from which calls were attempted at an earlier date. When attempting to make a successful call (not necessarily a successful interview) be sure to use the questionnaire with the number which is located immediately under the last four digits of the number you are calling on the phone number list. If the call does result in another busy signal or no answer return the phone number list to the "incomplete box for tomorrow" with the corresponding questionnaires. After attempts have been made on three separate dates to complete a busy signal or no answer that phone number is considered invalid and no longer constitutes a "call" so a new phone number should be attempted from the same list.

Glossary

Call back:

Contact has been made with someone at that number but completion of an interview was scheduled for a later date/time.

Complete:

A phone number which has resulted in a complete interview.

Incomplete:

A phone number which has not resulted in contact but is still a viable possibility for a completed interview (i.e. busy signal, no answer on first or second try only).

Invalid number:

A phone number which has been called three times without any contact or which has resulted in a refusal, non-working phone, nonresidence, or not within the city limits.

Required number of interviews:

Each phone number list has a number in the upper right hand corner indicating the number of completed interviews required for that community.

Exhibit B-3 (2 of 2)

IV. Selection of Adult Respondent from Household

The procedure used to select an adult respondent was taken from one developed by Troldahl and Carter (1964) and presented in Dillman (1978). It involves a matrix with entries based on the number of residents over 18 and the number of those over 18 that are men to locate the appropriate cell. Because no one choice matrix will provide a proportionate chance to all age and sex relationships in typical households, four versions were used, each identical with regards to the activities for the interviewer. The procedure is presented in the second page of the questionnaire (following).

Conduct of the Interview

Follows the format and content of the interview schedule, attached. Most were completed in approximately 15 minutes.

INTRODUCTION TO THE SELECTION PROCEDURE:

I am calling from a project at the University of Minnesota that is studying programs to control diseases killing the shade trees in many Minnesota communities, especially the Dutch elm disease. We would like to interview an adult from your residence about trees and programs designed to preserve them. This phone number was drawn at random from those in the community.

APPENDIX C

PROGRAM "MANAGER" INTERVIEWS

In order to develop a more complete description of the local shade tree programs, the context in which they operate, and relationships to the state program, interviews with program managers were considered an important source of information. Further, as one of the major issues for exploration was the failure of communities to participate in the state program, "managers" of programs that had dropped out of the state program or had never become involved in the state program were also interviewed: the last two types are considered non-participating cities. In each case there were two different issues related to the selection, choice of community and choice of individual to respond as program "manager."

I. Cities Participating in the State Program

As there were over 500 active local programs in 1980 it was clear that it would not be possible to interview the managers of all the programs; time and budget constraints seemed to allow for approximately one half to be included in the sample. It was considered desirable for the communities chosen to have the following characteristics:

- 1) Actively involved in the state program in 1980.
- 2) Involved in 1979 and having filed a year-end report.
- 3) Evenly divided with regards to size of the community (small, medium, large).
- 4) Distributed among the four major regions of the state (north, central, south, and metro area).

All cities that met these criteria were identified, as these include the 36 communities chosen for the citizen surveys they were also placed in the

manager survey sample. Remaining cities were chosen to be distributed among the twelve categories (3 sizes and 4 state regions) to represent the distribution of active programs in those categories (the percentage of sample in each category to equal the percentage of active programs in each category of community). In those cases where active programs exceeded the sample quota, communities were selected at random for inclusion within the sample.

All contacts with the city officials were initiated after a letter of introduction, describing the study, was sent to the program manager provided by the State Shade Tree program office. These letters were sent in groups of 60-70 over a four week period, one group each week. A copy of the letter is provided in Exhibit C-1.

For cities participating in the state program, interviewers first attempted to contact program managers. Telephone numbers were usually obtained either from directory assistance or from the 1980 Directory of Minnesota Municipal Officials. In smaller communities, interviewers initially called city clerks (because almost all cities listed telephone numbers for clerks), and in larger cities, interviewers initially called an appropriate agency of the city government (such as the Parks and Recreation Department) to obtain additional information about contacting program managers.

After contacting a program manager the interviewer either completed the interview or set up an appointment to do so. As the survey progressed, however, several changes became necessary: First, interviewers quickly discovered that program managers were not always well-qualified to answer the survey questions. In some larger cities, for example, the program manager had little knowledge of the actual operation of the program or the

UNIVERSITY OF MINNESOTA

Center for Urban and Regional Affairs 311 Walter Library 117 Pleasant Street S.E. Minneapolis, Minnesota 55455 (612) 373-7833

31 July 1980

The Center for Urban and Regional Affairs at the University of Minnesota, under contract to the Department of Agriculture, is conducting a study of shade tree programs. The objective is to examine the differences among the various shade tree programs in operation throughout the state.

Telephone interviews with the individuals who have operating responsibilities for shade tree programs are being conducted. These interviews will supplement what is already available in applications and reports. All information will be confidential and all participants will remain anonymous.

You may expect a phone call for an interview sometime during the next week. If you do not have the operating responsibility for the shade tree program in your area, please direct the interviewer to the correct person. A more convenient time for the interview can easily be arranged if you are busy when we first call. Should you have any questions about the project, please get in touch with any of the co-investigators listed below.

Thank you for your help.

William J. Craig
Assistant Director
Center for Urban and
Regional Affairs

Exhibit C-1 Letter of Introduction Sent to Program Managers extent of the diseases in the community since the role was strictly administrative; in some smaller cities the program manager was the city clerk, familiar with the necessary paperwork, but not with program activities as the primary responsibility for program operations were delegated to a tree inspector. In both of these cases, public officials other than the program managers usually were better able to respond to the survey questions because they were familiar with both the administrative and the operational aspects of the program.

Consequently, although interviewers continued to make initial contact with program managers, they found it necessary to determine the appropriate public official on a case by case basis. A short screening with self-selection sufficed: after contacting program managers, interviewers explained the purpose of the survey, provided an indication of the types of questions asked, and then asked whether the program manager felt his or her role made them qualified to respond to the survey, or whether another official would be more appropriate. Program managers frequently referred interviewers to tree inspectors on the basis of this initial screening.

Another change in contact procedures resulted from a necessary division of labor as more interviewers were used. In order to coordinate the effort, one person made the initial contacts and set up appointments, while others completed the actual interviews. This not only allowed one person to become familiar with special circumstances and situations where contact was difficult, it also facilitated a smooth scheduling of interviews. With a centralized interview schedule it was possible to disperse the numbers scheduled and also adjust the numbers of interviewers needed to the daily schedule.

Although most interviews were scheduled during regular office hours, small town public officials who worked in non-government jobs occasionally requested evening interviews; these were completed by the evening citizen interviewers. A more difficult scheduling problem arose when interviewers discovered that the selected public official served several communities (as either program manager or tree inspector) and was unwilling to be interviewed for each community. In these instances, interviewers attempted to select alternate officials but were usually unsuccessful; those communities seemed to be those where one individual operated the entire program and no one else had a great deal of knowledge about it. Therefore, officials from these cities were not interviewed.

Letters of introduction were sent to the officials listed in Exhibit C-2 representing local programs participating in the state shade tree program. As a total of 251 individuals were initially contacted and 239 eventually interviewed, the completion rate was 95 percent. There were very few direct refusals to provide the requested information.

II. Cities Not Participating in the State Program in 1980

For non-participating cities, a different selection procedure was used. The basic referenced list was a map where the participation status and population of each city in the state was indicated. From this map, a list of non-participating cities was prepared. Cities were selected to be interviewed by random sampling from that list.

The map was prepared using participation lists from the Shade Tree Program, Minnesota Department of Agriculture,* and the 1970 Census of Population. The Shade Tree lists enabled cities to be typed 1) always in program (in 1977-78 and 1980), 2) recent participants (in 1980, not 1977-78), and 3) dropped (in 1977-78, out 1980). All other cities listed in the Census were labeled 4) never in. The Census data permitted mapping each type by population size class.

Of primary concern here were city types 3 and 4: dropped and never in. For each of these types a separate list was prepared by scanning the map from north to south. These lists were further organized by city size class.

The sampling from these lists was stratified in two ways. First, higher sampling rates were used in the south.** More northerly cities had the excuse of no elms or no disease for not participating, while more complex answers would be necessary in the south. Second, higher sampling rates were used for the largest cities. Smaller cities had very low participation rates: largely due to lack of organization or resources. Larger cities would have more complex reasons. With about 30 cities to be selected in each city type 10 were to be large (900 or more people), 10 medium (400-899), and 10 small (under 400). The details of each sampling procedure are given below.

- 1. <u>Dropped</u>. Seventy-six cities were classified as having dropped from the program. Because of the nature of this class, the sample was naturally biased towards southern cities and no extra stratification was required.
 - a. 9 large cities -- survey each yielding 9.
 - b. 18 medium cities -- from a random start, select every other city yielding 9.

^{*}The current participants were listed in a brief handout entitled "1980 Participating Municipalities by County." Minor adjustments were made to this list subsequently. Earlier participation is noted in Report to the Legislature, 1977-78.

^{**}Roughly defined as south of the northern edge of Stearns county.

c. 49 small cities -- from a random start select every fifth city yielding 10.

The sample would then include 28 cities. Of these, one small and one medium-size city were subsequently returned to the program eliminating them from further study. In one additional small city, as might be expected, no contact could be made. The final sample then contained 25 cities. See Exhibit C-3.

- 2. Never in. Nearly four times as many cities (288) have never participated in the state Shade Tree Program. The preponderance of these were northern cities. The sampling procedure follows:
 - a. 22 large cities
 - 1) 2 from south -- survey each yielding 2.
 - 2) 20 from north -- from a random start select every third city yielding 7.
 - b. 59 medium cities
 - 1) 19 from south -- from a random start select every third city yielding 6.
 - 2) 40 from north -- from a random start select every eighth city yielding 5.
 - c. 207 small cities
 - 1) 57 from south -- from a random start select every tenth city yielding 6.
 - 2) 150 from north -- from a random start select every fiftieth city yielding 3.

The sample would then include 29 cities. One medium city insisted it had participated earlier and was not interviewed reducing the sample to 28. See Exhibit C-3.

The basic criteria for selection of public officials for interviews in nonparticipating cities varied somewhat depending on whether or not the city had ever participated in the state program. In cities that formerly participated, program managers were contacted to determine whether they actually had a good "working knowledge" of the program (that is, a familiarity with its creation and operation, and the nature and extent of the disease in the community) or whether their position as program manager was primarily an administrative title. After explaining that the question-naire covered a wide range of subjects that were not primarily technical in nature, or even after giving a sample of the types of questions asked, the interviewer asked for the person who could best provide this information. Frequently, particularly in larger cities, the program managers referred interviewers to tree inspectors or employees of the park and recreation departments.

In cities that never participated in the state program, interviewers sought the public official with the greatest knowledge of the community's shade trees, the diseases affecting them, or the community's decision not to participate in the state program. Most often, this was either the clerk or the mayor.

In all nonparticipating cities, however, the initial explanation of the general nature of the survey alleviated some of the feelings of inadequacy public officials had about their ability to comment on the technical aspects of the program or the diseases. The hesitancy to respond to questions on matters they were not familiar with, or questions which did not directly apply to their particular situation, presented far greater problems

than either the unavailability or uncooperativeness of the selected public officials.

Since we initially contacted the selected officials to set up appointments for interviews (at their convenience and up to one week in advance) most were available at some time; in fact, only one individual was unavailable and no satisfactory alternate could be found because he was the clerk/tree inspector/program manager.

Cooperation presented a somewhat greater problem, especially in smaller cities that formerly participated (the "drop-outs"). Public officials contacted at their place of work (nongovernmental) were almost all willing to be surveyed, for example, but they were hesitant to devote 30 minutes to the interview. If selected officials were unable or unwilling to cooperate, they were asked to refer interviewers to another appropriate official.

III. Conduct of the "Manager" Interviews

Once the appropriate individuals were identified within the community government, the interview was conducted in such a way to follow the schedule, attached. But the actual procedure was modified, depending upon the status of the community's shade tree program.

Communities currently in the state program. The interview schedule was designed for these communities and was followed as presented.

Communities that had dropped out of the state program. All references to the program were changed to the past tense in the discussion. Questions 6b, 18, 19, 25-27, 29, 30, 32, 33, 42, 44, and 50 were omitted from the interview as inappropriate. Depending upon whether the city

official responding was the city clerk or had served as tree inspector, additional questions may have been omitted as inappropriate.

Communities that had never been involved in the state shade tree

program. The occurence of elm or red oak trees was the first topic covered; if these were not present in the community, the interview was terminated. The first question was reworded, but the same issues were explored; why no program? The second question was modified to include only those types of pressures relevant for the specific community. Questions 3b, 4, 6b, 7a, 7b, 10-11, 15, 16, 18, 19, 22-27, 29-35, 38, 41, 42, 44, 48-51 were omitted from the interview. Many of the responses were somewhat ambiguous; officials were obviously trying to be cooperative but had few judgments indicating strong confidence in either their knowledge or opinions. Many considered that most questions did not apply to their situation.

APPENDIX D

CASE STUDIES OF COMMUNITY PROGRAMS

The eight case study communities are denoted by an asterisk in Exhibit B-1, the table of focus cities in Appendix B. The selection criteria were the same as those for the focus cities, reflecting a desire to maximize variation on success ratings (by state inspectors), community size, and region of the state. Thus, communities were chosen with regards to success as follows:

High ratings, congruent: Lakefield, St. Cloud

Moderate ratings, congruent: Hanley Falls

Moderate ratings, incongruent: International Falls, St. Paul

Buhl, Dayton

Below average ratings, congruent: New Ulm

Further size was varied as follows (based on 1970 census):

Large (over 10,000): New Ulm, St. Cloud, St. Paul

Medium (2,001 - 10,000): Dayton, International Falls

Small (200 - 2,000): Buhl, Hanley Falls, Lakefield

Finally, region was varied as follows:

Terrible ratings, congruent:

Metro: Dayton, St. Paul

North: Buhl, International Falls

Central: Hanley Falls, St. Cloud

South: Lakefield, New Ulm

Note that there are no two cities from any one cell of Exhibit B-1. In this way, the maximum amount of information may be obtained from the eight case study cities as representative of the 36 focus communities, the 36

focus cities represent, in turn, the hundreds of cities with local shade tree programs.

In each community the observer was instructed to interview the program manager, the mayor or city manager, a newspaper reporter (if any) covering the topic, the tree inspector, the tree remover, city council members (if identified by the mayor as interested in the program, neighborhood groups (if identified by other respondents as interested in shade trees), nurserymen (if available), and anyone else identified as active on the issue by the other respondents. Appointments with city officials were made in advance by phone; additional appointments were made during the visit. Some follow-up interviews were also completed by phone. The basic format of the interview was to administer the program manager survey (see Appendix C) with some open-ended questions added and with some changes depending upon whether the person was a technical expert (tree inspector, nurseryman, tree remover, program manager) or a generalist (mayor manager, council member, newspaper reporter, neighborhood group leader). If the individual was a technical expert, the questions dealing with the disease were stressed, whereas if the individual was a generalist, the questions dealing with the history of the program and citizen participation were stressed.

The format allowed for comparability across classes of respondents and cities since the same basic questions are asked of individuals occupying the same roles in different cities. The open-ended questions allow for unique items to emerge which explain how each city differs in its problems or how different individuals can explain the same event. The format provides a vehicle for comparing how individuals in different roles perceive the program and its success. It is possible to determine the extent to

which the program manager's perception of a program and its importance is shared by tree experts in the same city and generalists who have other concerns besides the community forest.

Following are summary descriptions that were developed for each of the eight communities, arranged alphabetically. The descriptions were based on a review of the interviews and other material available on the programs and their stature in the community. BUHL

Buhl is a small town (1303 people located in northern Minnesota on the Iron Range. Its programs were rated as terrible. Reasons for its lack of success are important because the disease is spreading throughout the northern part of Minnesota.

In Buhl the disease took off in 1978, after the state program had started. Thus, Buhl could benefit from the lateness of the attack. It has no wild elm problem and nearly all the elms are routine to remove. It should also be pointed out that elms make up a smaller percentage of the total tree population than in many other cities. There are fewer elms on private property than statewide and so far only 4 or 5 of them have been infected. Yet, the disease is advanced on public land: this year about 20 trees will be removed, but that is 20% of the elm population lost in one year. Clearly, Buhl is lagging behind in fighting the disease.

There were more complaints about citizen disinterest and about city employees' lack of support than in the other cities we visited. Enthusiasm seems to be concentrated in the program manager (who is also the tree inspector and street superintendent) who seemed beleagured by the problems he encounters. Reputedly, city employees who remove trees hate it and fight it; in no other city was the danger of the tree removal job stressed so much. The citizen survey disclosed that residents participated less than average except in watering the trees the city had put out. Of course, when the disease has not yet hit individual property owners, it is hard to get the citizenry excited about the problem. Buhl citizens did rate their city's program a little lower than did the average Minnesotan so its shortcomings are obvious to residents. Buhl residents, at least those in the survey, were younger, more educated, and had higher incomes than the average

Minnesotan, so one would expect more support from them for this program.

The main reason cited for the program's failure is lack of money and manpower. The trees are removed by the street department which has many other responsibilities during the summer months. Thus, the city does not have enough employees, we are told, to get the trees cut down in time. They also say that they do not have enough money to hire private contractors to do the job for them. Again, given the socioeconomic composition of the citizens we surveyed, it is hard to understand why the city can't afford a better program. One positive aspect of the program's operation is the cooperation with other Iron Range cities in purchasing equipment.

The sanitation program operates as follows: the city removes trees on public land and on boulevards; it provides no reimbursement to private citizens for removing their own trees but of course that hasn't been a problem thus far. About 20 trees were lost in 1980 but that is a high rate of loss (20%).

The replanting program involves the city's replanting on public land and on boulevards. The city will replant 30-40 trees this year but apparently they are behind from past years when many trees of other types had to be removed. The setup of the program is no different from that of the more successful programs but the level of effort is apparently less. If citizens and elected officials do not become more interested as the disease hits harder, Buhl is in for near total elm tree losses. Yet, that may not be as devastating as in St. Paul because Buhl has a more diverse population of trees.

Dayton is a medium size community (2675 people) located on the fringe of the metro area. It contains farm and residential areas within the city limits. Its sanitation and replanting programs were both rated as terrible by state inspectors. Are there lessons to be learned from its experience?

Dayton is required by the Metro Council to be in the state program but otherwise Dayton probably wouldn't be participating. The state program allows reimbursal for tree removal from state funds only to residents who own less than 5 acres of land. Since many Dayton residents don't fit these requirements, Dayton doesn't reimburse anyone with state funds. The program doesn't fit Dayton, they feel, so they participate somewhat grudgingly.

Dayton's disease problem is probably more difficult than that faced by the more successful cities we looked at. In the citizen survey, more citizens reported having elms on their property and on adjacent public land than did the average Minnesotan. Similarly, more citizens reported having had trees removed and replanted than the average Minnesotan. Officials believe the number of wild elms bordering the city to be a significant source of disease. These wild elms are located along two rivers which border the city and on farmland in a neighboring township which does not participate in the program. The number of farms in the city, with large numbers of elms, is also a major problem for Dayton. In some cases the owners of these farms are elderly persons who simply can not afford to have large numbers (in some cases 50 to 100) of diseased elms removed from their property and are unable to do the removal themselves. In such cases, the city does not feel that they can force the property owners to remove the

trees. The manager reports that only 50% of elms can be routinely removed, a very low percentage,

A contributing factor is that the tree program is not salient to individuals and groups in Dayton. On the one hand, citizens rated trees as important (more so than did the average Minnesotan) and rated Dutch Elm Disease as an important threat. Yet, individuals hadn't done much about this perceived threat: none had watered new trees and none had joined in a group to contact the government (whereas in other cities there was at least some one who did these things). Compared to other Minnesotans, the citizenry of Dayton gave their shade tree program a low rating (congruent with the state's rating of it) and gave their government in general a low rating.

This low salience and discouragement is especially manifested in city officials. Even among people who were supposedly involved in the program, there was little knowledge and awareness. The city government is very small, mostly part-time people, who feel that the state program doesn't fit their needs and who feel that they are battling against great odds. Contrary to the successful programs, they feel that their city wouldn't continue its program if state funding ceased. A significant problem for them is the lack of resources, which is remarkable since Dayton citizens reported the highest income average in our case studies. Perhaps their most severe resource problem is in manpower. There are just too few city employees to enable Dayton to remove trees quickly.

The program is a very small operation. City crews remove diseased trees on public property and boulevards, if possible; if not, they hire a private contractor. The same contractor removes trees on private

property (unless the owner does it himself/herself) but there is no reimbursement. About 100 trees were removed in 1980.

The city will replant slightly more than it takes down in 1980. For public areas, the city buys the trees but does not plant them; instead, it relies on volunteers to do the planting. About 75% of the residential property owners do replace trees on their own.

The unsuccessful program in Dayton has twin causes: it has a significant disease problem due to the mix of farm and residential land which is not adequately covered by state regulations; no one wants to be in the state program; therefore, little money is spent and not much is done.

HANLEY FALLS

Hanley Falls was rated as having an average program both in terms of sanitation and replanting. It is a small city (265 people) in south central Minnesota. What seems to account for its success rating?

Hanley Falls is typical of many cities in its region—the disease has already taken 80% of its elms so there is not much left to manage. The disease takeoff point was probably in 1976; at that time, 75% of the city's trees were elms. Now only about 25% are elm. Nearly all the elms are located in places where they are routinely removable. As expected, its citizens report a below average number of trees on their own property and on adjacent public land. They believe the threat from the disease is more important than does the average Minnesotan. Thus, Hanley Falls does not have a huge removal job facing it.

Hanley Falls is remarkable for its citizenry. They report participation (removing trees, replanting trees, watering trees, etc.) above the Minnesota average. They have more knowledge about their city's program than does the average Minnesotan. However, Hanley Falls residents are below average in education and income and above average in age. We have seen in other communities that older and poorer citizens are less interested in the shade tree program because its pay-off lies in the future. Similarly, city officials are remarkable. The mayor takes an active interest in the program and several groups have helped to replant trees. The tree inspector in this small town drives by every tree almost every day, watches for signs of disease, and marks trees immediately. Other city officials think that he is very competent.

The sanitation program operates as follows: the city removes a few trees (20%) but normally hires a contractor to take out diseased trees from

public land, boulevards, and private property. If the tree is on private property, the city assesses the homeowner for the cost of removal above that provided by the state subsidy. The city does not provide any subsidy of its own but does pay for disposal. The city replants trees on public land and on boulevards. It has replanted about 40 trees this year, about the same as the number of trees to be taken down in 1980. Hanley Falls residents are unique in that they gave a higher priority to replanting (versus chemical treatment and removal) than did any other city in the case studies. Again, this is unusual, given the average age of its residents.

One way to look at Hanley Falls is that its programs are average. However, it is probably doing better than it should be doing (based on its demographic characteristics and its size.) It will probably never attain high success because most of its trees are gone and it lacks money to provide the highest level of financial incentive to its citizens.

INTERNATIONAL FALLS

International Falls is a medium-size city of 6400 people located in northern Minnesota. The incidence of disease is fairly new to the northern portion of our state. The city's sanitation program was rated as highly successful but its replanting program was rated much lower. What lessons can we learn from its sanitation experience and how can its replanting program be improved?

The disease problem faced by International Falls is less than that in the southern regions of the state. The disease reached International Falls relatively late, after the state program had already started (probably the take-off point was 1978). Thus, this city could benefit from the experience of other cities in fighting the disease, from the state money, and could keep up with the progress of the disease. Secondly, most of the diseased trees so far have been on public land and are routine to remove. International Falls residents reported markedly fewer elm trees on their own property than did the average Minnesota residents. Also, the density on public land is reported to be less than average.

There are two elements which cause the disease control program some difficulties. First, officials mentioned the long border shared with South International Falls which has a lot of untreated elms. Officials think their program would work better if South International Falls would participate in the program also. Second, the summer is very short in International Falls. Disease can't be observed until sometime after June 15 because trees aren't leafed out. At that time, city personnel are busy with other outdoor work and don't have much time to devote to trees. Still, given the program's high rating, officials seem to be overcoming these two difficulties. If the disease had hit earlier or harder, their success might have been less.

International Falls is particularly strong in the concern and attitude of its city officials. A few officials had urged a shade tree program for years and were important in the city's joining the state program. The city council president had attended seminars on the disease before the city joined the program. In addition, a county agricultural agent who lives in International Falls and is knowledgeable about trees has been active in advising the city about its program. The tree inspector is a retired forester of whom everyone thinks very highly. The City Council has been very supportive of the program; several members are self-proclaimed "tree lovers." In fact, the council recently agreed to fund chemical treatments before they knew that they could be reimbursed for half of the cost. Hence, this city was not one which joined just to get the state money.

Similarly, citizens display more than the average amount of concern, even though the disease has not yet hit their city hard. They rated the importance of trees higher than did the average Minnesotan. They rated the threat of the disease to their city as high as did the average Minnesotan, even though the disease is not as advanced here as elsewhere. Residents of International Falls were below average in the number of actions taken on behalf of trees: this is understandable because they do not have as much opportunity as other Minnesotans. Most importantly, they were willing to pay more in additional taxes for a shade tree program than was the average Minnesotan. This is unusual given their modest exposure to the disease and their modest elm stands.

In terms of the actual operation of the disease control program. International Falls does not fund much removal, whereas, we found funding to be crucial to the success of other programs. City crews do remove diseased

trees on public property, but boulevards and private property are the responsibility of the homeowner--there is no reimbursement by the city, even from state funds. The program manager and tree inspector said that the city council had not set up a reimbursement program because they were very reluctant to involve the city with private property in any way because of liability fears. They also said that they didn't think the city council understood that they could set up a reimbursal program that would not require city crews to do work on private property. So far, most of the diseased elms have been on public property (about 20 in 1980) so very few residents have had to pay for tree removal. The tree inspector and program manager think that when the number of diseased trees on private property increases the city council might change its position on reimbursal. To some extent, the city has been lucky so far; if the disease worsens, they may have to increase their expenditures in order to continue their success in controlling the disease.

Although the replanting program was rated as low, the picture seems somewhat different from the perspective of International Falls. The city had already started a program of planting trees on public lands before they joined the state program. City crews replant trees on public lands and boulevards and say they will replant more than they lost in 1980. About 50% of private losses are replaced. Residents do report more than the average number of trees replanted on their own property but only an average number replanted by government. Residents also report a higher than average frequency of watering boulevard trees.

One area which could stand improvement is in citizen awareness of the shade tree program. A higher than average number of citizens responded

"don't know" to the questions about the program. Perhaps a public relations campaign would increase citizen participation in both aspects of the program. This seems promising, given the favorable attitude of residents toward their trees.

LAKEFIELD

Lakefield is a small city (2000 people) in southern Minnesota whose sanitation and reforestation programs were rated in the highest success category by inspectors. What makes Lakefield different from the many other small cities who are having trouble with their programs?

Lakefield is unfortunately a town for whom the state program came too late. The disease took off in 1974, three years before the program started; by 1980, 70% of the original elm population was lost. Thus, a relatively small population of trees remains whose incidence of disease the city is now able to control. Furthermore, infection from wild elms is not an important problem because most of these elms are dead too. Of the remaining elms in the city, 75% are in locations which allow for routine removal.

One important factor in Lakefield's current success is the attitude of its citizens. Lakefield citizens, more than the average Minnesotan, think trees are extremely important, have reported infected trees, and replaced trees. Compared to the rest of Minnesota, more of them have worked in groups to remove infected trees and to replant trees. They were much more likely to support paying an additional tax to keep the program going. Whereas most citizens rated their shade tree program about the same as their local government in general, the people of Lakefield rate their tree program higher than they rated their local government. Program officials agree that citizens are cooperative and good about reporting incidence of disease.

The operation of the program is characterized by speed in inspection and removal--all trees are inspected by June 15--and removed within 10 to 20 days, according to city officials. This speed is possible because

it is a small town with relatively few remaining elms. The city hires a private contractor to remove diseased elms on public land (including boulevards) and private property, though the property owner pays for the removal with 45% matching by the city. This subsidy is important to the success of the program because senior citizens make up a large and growing segment of the population of Lakefield. In the opinion of city officials, senior citizens could not afford to pay for tree removal without the subsidies. The city pays for disposal of both public and private elms. Trees are also marked again in the fall. 25 trees were removed in 1980.

The city pays for replanting trees on boulevards and in parks. It hires a nursery to do the planting so that the new trees are planted properly. According to the nurseryman who does the planting, the citizens do a good job of caring for and watering the trees and most of the new trees stay healthy. In 1980, it planted 30 trees, more than were cut down. About 75% of homeowners replanted trees, according to the mayor. In our sample of citizens, only 34% reported having planted a tree, but this is higher than the state average.

City officials in Lakefield think that keeping the citizens of Lakefield well informed about Dutch Elm Disease and care of trees is important to the success of the program. The city has cooperated with the local newspaper to make such information available. A city council member said that the mayor is very knowledgeable about trees and willing to advise citizens about how to care for their trees or to get someone in the street department to answer their questions.

Lakefield's program is organized quite a bit differently from the other successful program in a large city--St. Cloud. In Lakefield, city employees do not preform much of the actual work but instead contract it out, since the work is on a smaller scale than in St. Cloud's. This arrangement between the public sector and the private sector works quite well. The other difference from St. Cloud's experience is that Lakefield's citizenry is more supportive than St. Cloud's citizenry. Thus, citizen support and involvement may be more crucial in a smaller setting. The two successful cities are similar in that the disease is not as severe as elsewhere (though for different reasons).

NEW ULM

New Ulm is a city of 13,051 residents, placing it in the lower range of our large cities. It is located in southern Minnesota and its sanitation and replanting programs were both rated as below average. What can we learn from its experience?

The disease problem faced by New Ulm is moderate: the disease most likely took off in 1977; thus, the state program came just in time. Officials say that wild elms nearby are a major problem and that only about half of the diseased trees can be routinely removed. Elms in ravines on private property are among the elms that are very difficult to remove. They were included in the disease control program because they are located primarily on the property of higher income citizens and the city council thought that it would be unfair to require low income residents to remove their diseased elms and exempt some wealthier land owners from having to remove all of their diseased trees. Thus, New Ulm faces a nontrivial disease problem, but it is not insurmountable by any means, nor as great as that faced by other cities.

The next area to examine is community attitude toward the disease and the program. There is some suggestion by officials that New Ulm entered the program only because of the financial incentive offered by the state. Some have said that the city council is not too involved in the program because the members are beset by other pressing problems. Others said that publicity hasn't been effective in reaching the citizens and making them aware of the program. The responses to the citizen survey belie this report: compared to the rest of the state, New Ulm residents perceive a greater threat from the disease, report a higher rate of chemically treating their trees, of removing their own trees, of replanting their own trees, and rate

their city's program highly. On other dimensions, New Ulm residents are right at the state average: in care of the city's new trees and in know-ledge about the program. On the whole, it seems that while citizen support is not among the highest in the state, it is more than adequate for a good program. New Ulm residents are not apathetic about their trees.

The remaining area is the program itself. This is the area which could stand improvement. In terms of sanitation, city crews remove diseased trees on public land, but admittedly not always soon enough because the park department has many other responsibilities during the summer when removal is done. Boulevards are treated much the same as in private property: private contractors remove the trees at citizen's expense, with the city reimbursing 50% with a maximum of \$75 per tree and a limit of 3 trees per owner. The maximum and limit do not apply to the boulevard. At times, there are not enough contractors to get the private trees removed quickly enough after they have been marked. Treating the boulevard as a public responsibility might significantly improve the disease control aspect of the program, but according to the city manager, the city council is reluctant to do this both because of the increased financial commitment it would involve and because treating the boulevards as private property has been a long standing tradition in New Ulm. About 1000 trees were removed this year.

Replanting responsibilities are handled in the same manner: city crews replant on public land; on the boulevards, the city pays half the cost of planting up to a \$30 maximum. When this program was established, the philosophy behind it was to maintain a sense of responsibility for the boulevard trees on the part of the home owners. It was thought that if they had to pay part of the cost of planting, they would be more likely to

water and care for the tree, but this partial subsidy has resulted in only about 30% of the boulevard trees being replaced each year. Also, the city places limits on the type and size of tree it will pay for. All of the city officials interviewed expressed disappointment over the fact that the replanting subsidies have not been more successful in encouraging boulevard planting. Several said that there was a communication problem between the government and the citizens; that many citizens did not even know about the subsidies. The city does place ads in the local newspaper describing the subsidy program, but apparently this has not been sufficient. According to officials, an additional significant problem is that in areas where the most elms have been lost, the residents are largely elderly or low income and do not replant trees. The elderly say they won't be around to enjoy the trees; other low-income residents can't afford the cost or don't think it is important. Both officials and citizens care about the program but the city will have to make it a higher financial priority before the program will be successful.

ST. CLOUD

St. Cloud's sanitation and replanting programs were both rated in the highest category by state inspectors. It is a city of 42,000, located in central Minnesota. What can other cities learn from its experience?

First, St. Cloud appears to be blessed with a less severe problem than many other cities. It has very few (1%) wild elms bordering the city. Within the city, although the elm population is slightly higher than the state average, the elm trees are less likely to be found on private property and more likely to be found on public property, compared to the state patterns. The physical location of elms is such that they are easy to remove.

A second possible factor is citizen attitude: residents of St. Cloud, more than the average citizen, consider the disease to be a major or important threat to their neighborhood, even though actually the disease is not a big threat. Yet, the residents are not more likely than the average Minnesotan to have taken action to help trees or to lobby government, or to have information about the program. Similarly, the present mayor is not particularly enthusiastic or knowledgeable about the program, though supportive. Thus, St. Cloud's program is succeeding despite citizens and their elected leader.

The most important factors seem to be the enthusiasm of city employees in the tree program and the fact that resources are adequate to keep ahead of the disease. Tree inspections are done early in the year and frequently. City crews remove trees on both public property and boulevards; on private land, the owner hires a contractor and is reimbursed 45% of the cost of removal, up to \$50 per tree.

The tree inspector said that when the program first began, citizens protested when they were informed that they had to remove one of their

trees, and delayed doing so, but now everyone seems to recognize the importance of removing trees quickly. There is sufficient manpower to remove trees quickly, even though they are dealing with 750 trees in 1980. They are now losing only 2% of their elms a year.

Similarly, replanting funds are more than adequate: the city will replant 1680 trees in 1980, more than twice the number taken out. Sufficient funds to replant more trees than they remove have been available for several years. There is no public subsidy for replanting on boulevards, but even so, about half of these diseased private trees are replaced every year. In regard to boulevard trees, the city has the "steward" concept: citizens file a permit to replant on boulevards; the city sets the size of the tree and range of species which can be planted: the citizen plants the tree and has the responsibility of being its steward for 5 years, after which the city accepts responsibility for its maintenance. The tree inspector said that this program has some advantages in that it encourages citizens to take care of boulevard trees, but he also said that the replanting program would be more successful if the city assumed responsibility for replanting on boulevards. Occasionally, the city council will order that a whole block be replanted. This usually occurs only when a new housing development is built. Some local groups have helped in replanting such as the Trades and Labor Union, the Kiwanis Club, the Girl Scouts, and the Boys Club.

The city park department seem to run the program very quietly and efficiently without much involvement of city elected officials. In the past, the mayor and the city council were deeply involved in more controversial issues and did not give the shade tree program much attention, but

they did fund it adequately. St. Cloud is a good example of what adequate manpower and resources in a large city can do, even without a great deal of citizen support.

ST. PAUL

St. Paul is the state's second largest city (309,000). Its sanitation program was rated low but the replanting program got a high rating. What can other large cities learn from its experience?

St. Paul has lost more elms than any city in the state: 105,000 of an original population of 131,000. In 1975 St. Paul lost 2,000 trees, 19,000 the next year, and in 1977, the year the state program started, it lost 47,000 elms. Since then, losses have fallen to 15,000 in 1978, and then to 6,500, and 4,000 this year. Although the state program began in part because of the visibility of St. Paul's problem in the capital city, the program was too late for St. Paul. Just at the time the program was getting off the ground, losses jumped from 19,000 to 47,000, making it difficult to get marked trees down in time. Everyone connected with the program admits that it was not run as well as it could have been in the early years, but funds were inadequate to cope with a problem of this size and the logistics of trying to remove and dispose of that many trees in one year created problems that just could not have been forseen.

St. Paul's elm concentration was unusually high, 85% of the trees in the city were elms originally. Wild elms along the Mississippi River still pose a problem as does the nonroutine nature of removal since so many trees are in yards. The low risk trees frequently do not come down for some time, often well into the winter. The program manager said that tree removal firms are unwilling to add the extra men and equipment that would be necessary to remove all the trees quickly and they will only work on a year long basis.

St. Paul began replanting trees in 1972 and in the last three years it has replaced more trees than it has lost. Still, it is behind because of the huge losses in 1977. There is reluctance to allocate more money to

replanting because the removal expenses have drained the public works budget in the past few years. Little street repair has been done, for instance.

St. Paul has made a substantial commitment of its own to the program: 30 million dollars over the past three years. The mayor has been especially enthusiastic about the shade tree program and the city's financial involvement in it. Initially, neighborhood groups were involved in chemical treatment and replanting but city officials are disappointed in the current level of interest of citizens and neighborhood groups now that the crisis has receded somewhat. Both the program manager and the city's foresters have gone to neighborhood meetings in recent months to try to stimulate interest in the program, particularly replanting, but feel that they have not been successful.

Yet, the citizen survey reveals a citizenry which is more interested than the average Minnesotan. St. Paul residents rate the threat from disease higher than the average Minnesotan. Their self-reported participation is about average as is their organizational involvement directed toward trees. On other participatory dimensions they are above average: watering trees planted by the city, individual efforts to influence government on trees, and knowledge about their city's programs. Thus, the decline in interest perceived by the city officials is only in relation to St. Paul's past performance, not in relation to the rest of the state. St. Paul residents are average in income and education but younger than other Minnesotans. Hence, St. Paul would seem to have the ingredients for a successful program: an interested citizenry and elected officials.

The operation of the program proceeds as follows: diseased trees on public land and boulevards are removed by city crews. The private property

owner in St. Paul has a unique advantage; the city hires private contractors to remove the private trees and pays for the full cost of removal. The mayor recommended to the city council that this system of free residential tree removal be established and was successful in convincing the council to adopt The mayor said that the program was set up in this manner for two the plan. reasons: to avoid creating financial hardship for low income residents, and because the council agreed with his opinion that the trees in the city should be regarded as a community resource of benefit to everyone, not just the property owner. We can presume that without this substantial public commitment St. Paul's losses would have been nearly 100%. The officials connected with the program think so. They also think that they are able to run a more efficient program by contracting all the removal at one time rather than having each property owner arrange on his own for removal. According to newspaper accounts, St. Paul paid a higher unit cost for both removal and replanting than did Minneapolis, in part because St. Paul paid union scale wages and other cities did not.

The replanting program is fairly typical: the city pays for planting on public land and boulevards, with private nurseries doing all the planting (which runs up the cost but may increase the longevity of the tree). Property owners are encouraged to plant on the boulevards also, but must obtain a permit to do so and are restricted as to what types of trees can be planted. The city will plant 6000 trees this year. Essentially, replanting is the only area in which St. Paul has a chance to succees, having lost so many trees in earlier years.

APPENDIX E

STATE SHADE TREE PROGRAM FORMS

Two major sources of data were the forms completed by local programs for submission to the state shade tree program. The annual report forms were the source of substantial data on program activity; similar forms were the basis for data from the previous years (1977, 1978). Information provided on the applications for 1980 program acceptance were used as a source of information regarding plans for program operation. Both forms are provided in this section.

SHADE TREE PROGRAM REPORT

AGREEMENT

By and Between the

MINNESOTA DEPARTMENT OF AGRICULTURE (Hereinafter "department")

	and	:
		(Hereinafter "grantee")

WHEREAS, Minn. Stat. § 18.023 provides funds on certain conditions for grants to local units of government for shade tree sanitation programs on public and private lands and for reforestation on public lands, and

NOW THEREFORE, department and grantee in consideration of the respective promises contained herein agree as follows:

- 1. Subject to legislative appropriations and aggregate demand department shall pay grantee up to 50 (%) of the cost of grantee's sanitation and reforestation program.
- 2. Grants to certain cities, counties and towns may include 90% of the cost of the first 50 trees planted under the grantee's reforestation program, if the grantee qualifies for such payment under Minn. Stat. § 18.023 (Supp. 1979).
- 3. Grantee shall submit quarterly requests for payment to department setting forth all information required by department.
- 4. Grantee shall fully comply with Minn. Stat. § 18.023 (Supp. 1979) and all rules promulgated pursuant thereto and shall maintain business records in conformance with generally accepted accounting and auditing principles to fully evidence its costs and expenses and allow department full access thereto. Any cost incurred for an activity not in compliance with such said statute and rules shall be ineligible for reimbursement. Grantee agrees to promptly return all funds which have been paid to grantee by department for any costs incurred in violation of the terms of this agreement of the said statute and rules.
- 5. Grantee represents that none of its officers or employees has any financial interest in this contract or proceeds payable thereunder.
 - 6. This agreement shall cover the period January 1, 1980 to December 31, 1980.

IN WITNESS of this paragraph

7. The department may make supplemental grants or setoffs in the event of changes in grantee's budget and actual expenditures.

APPENDIX F

SUPPLEMENTAL DATA FROM OFFICIAL SOURCES

In addition to data generated specifically for this project, a good bit of relevant data was extracted from other sources. All this data was extracted from state and federal files. Where possible, computerized files were referenced to facilitate a merger of this new information with the primary data. Each supplemental data element is listed below along with the rationale for its use. In addition, the source of each item is documented. State government data concerning the Shade Tree Programs and their effectiveness have been documented in Appendices 1 and 3.

I. Size of City

- A. <u>Population</u>. Smaller cities often do not have a sufficient governmental structure to operate a program such as one for shade trees. Furthermore, they tend to be more homogenous with less likelihood that a person will step forward to lead an effort to save their trees. People will be more self-sufficient and less reliant on government. Finally, there will probably be fewer trees to save.
 - 1. 1970 population -- Census of Population (MEDlist computer tape).
 - 2. 1975 population -- Census Bureau estimates generated for revenue sharing purposes. Extracted from computer tapes by the Minnesota Analysis and Planning System (MAPS).
 - 3. 1978 population -- same source.
- B. Land Area. The larger a city, the more area it probably needs to police. Area measurements are not regularly available and were pulled together from a number of sources. Census measurements from 1960 (GE-20, No. 25) were used as a base. For the state as a whole these had been roughly updated to 1970 using county highway maps. All substantial changes to 1980 in the metropolitan area were incorporated using data from the Metropolitan Council (Resource and Development Report No. 3).

Newer cities or portions of cities are less likely to be planted with elms. On the other hand, growing cities may have more energy to tackle a municipal problem.

A. 1970 Age Distribution of Housing Units. Number of units built before 1940 and in each decade following was

A. 1970 Age Distribution of Housing Units. Number of units built before 1940 and in each decade following was extracted from the 4th Count Census Housing Tape by MAPS. This data was easily available for cities of 2500 or more and extracted for those cities only. See comment below.

- B. Population Growth. The difference between the 1978 estimate and 1970 count was available for all places. The percentage change was used as a surrogate for age of housing in smaller communities.
- C. Median Age of Population. Extracted from 1st Count Census Tape by MAPS.

IIL Percent Homeowners

Theoretically, homeowners have a vested interest in their neighborhood and are more likely to support a shade tree program. Tenure of occupied housing units was extracted from the 1970 1st Count Census Tapes by MAPS.

IV. Potential Magnitude of Problem

A number of measures were put together attempting to measure the potential magnitude of the shade tree problem facing each city.

- A. Elm and Oak Inventories. See Appendix E.
- B. Land in Parks. Municipal park land is the responsibility of the city. The more acres of parks, the greater the need of a city to have an effective shade tree program. Current data on acreages of municipal parks was printed by the Department of Natural Resources (DNR) from their SCORP file.
- C. <u>Incubation Areas</u>. The undeveloped land in and adjacent to each city provides a breeding ground for elm beetles where no sanitation program is removing diseased trees. Cities surrounded by such forests may abandon hope.
 - 1. Manager survey -- managers were asked to estimate the percentage of their municipal borders in wild elms as well as the health of these trees.
 - 2. External sources unfortunately no source of this desirable information exists. DNR tree inventories are appropriate to the county level of geographic specificity only. Finer geographic coverage is

available from the North Central Forest Experiment Station but only for an elm-ash-cottonwood association. This latter measure was deemed more appropriate for this work. A data file was extracted from the Minnesota Land Management Information System (MLMIS) by the State Planning Agency staff.

- a) Acres and Percent Elm-Ash-Cottonwood Within City Limits.
- b) Same for Land Adjacent City.
 - 1) On Municipal Border
 - 2) Within ½ Mile
 - 3) Within 1 Mile
- V. Ability of City to Cope With Problem

Many measures were deemed important indicators of the cities' ability to run an effective program.

- A. Form of Government. Some forms may be more effective than others. Form coded form Minnesota's Bluebook.
- B. <u>Size of City Government</u>. Larger governments may be in a better position to tackle a special problem.
 - 1. Budget
 - a) Total Revenue Extracted from 1977 State Auditor File by MAPS.
 - b) Total Expenditure. Same Source.
 - c) Forestry Budget. 1979 Shade Tree Program Reports.

2. Staff

- a) Number of (FTE) Shade Tree Employees. 1979 Shade Tree Program Reports.
- C. Ability to Pay. Poorer, more highly taxed people will probably be less willing to support a program aimed at amenities.
 - 1. 1974 Per Capita Income

Extracted from 1975 Revenue Sharing tape by MAPS.

2. Local Taxes

Extracted from 1977 State Auditor File by MAPS.

- a) Tax Levy
- b) Special Assessments. Used by Many Cities to Supplement Ongoing Programs.

3. Total Indebtedness

Extracted from 1977 State Auditor Indebtedness File by MAPS.

4. Special Forestry Levy

1979 Shade Tree Program Reports.
