Perceptions and coping strategies of dental hygienists practicing during the COVID-19 pandemic

A THESIS SUBMITTED TO THE FACULTY OF
THE UNIVERSITY OF MINNESOTA

BY

Shelah Amanda Christensen

IN PARTIAL FULFILLMENT OF THE REQUIREMENTS
FOR THE DEGREE OF
MASTER OF SCIENCE

Dr. Cynthia Stull, Advisor

February 2022
ACKNOWLEDGEMENT

I would like to thank my advisor, Dr. Cynthia Stull for her academic and personal support throughout this process. This project would not have been possible without your time, feedback, and encouragement every step of the way.
DEDICATION

I would like to dedicate this thesis to my husband Jon, who always supports my endeavors and is an invaluable sounding board. To my daughter Helena, who was born during this process, and to my sister, Grace, for her support. I would not have gone, or stayed, on this journey if it wasn’t for God’s guidance and timing.
ABSTRACT

Purpose: This study investigates perceptions and coping strategies used by dental hygienists during the SARS-CoV-2 (COVID-19) pandemic, March 1, 2020 until present. The Transactional Theory of Stress and Coping was used as the framework for this study.

Methods: An electronic questionnaire (Qualtrics™) with questions in three domains: demographics, perceptions, and coping strategies, was emailed to dental hygienists in five Midwest states, summer of 2021. Participants were asked to indicate perceptions of and coping strategies used, while practicing during the COVID-19 pandemic since March 1, 2020. Bivariate comparisons between respondent demographics and survey responses regarding coping, risks, and strategies were computed using Fisher’s Exact Test. Survey responses were both analyzed as the original 5-point Likert scale and a collapsed 3-point Likert scale assessing overall agreement, disagreement, and neither agreement nor disagreement.

Results: Completed questionnaires totaled 167, with a 4.4% response rate. Majority of respondents were white females aged 56 or over, were employed full time, and had been in practice for ≥ 21 years in private general practices. Reduction in working hours was reported by 8.4% of respondents, and 7.2% reported leaving the profession. Perceptions of practicing during the pandemic were reported as experiencing increased risk of infection, a threat to the health of self, family/loved ones, and more physically demanding. The vaccine aided in reducing risk perceptions. Adaptive and maladaptive coping strategies were used while practicing during the COVID-19 pandemic.

Conclusion: Dental hygienists perceive practicing dental hygiene during the COVID-19 pandemic as putting themselves and family/loved ones at risk of contracting the virus. Respondents reported dental hygiene practice is more physically demanding than before.
the COVID-19 pandemic and dental hygienists are more agitated and worried. Dental hygienists are finding ways of coping with these stresses by engaging in practice to improve mental health, using personal relationships for support, exercising, turning to spirituality, and using social media more than before the pandemic. Dental hygienists in this study reported reduced hours of work or leaving the profession, contributing to workforce attrition.

SECTION 1
INTRODUCTION

On December 30, 2019, in Wuhan City, Hubei province, China, a bronchoalveolar lavage sample was taken from a patient with an unknown form of pneumonia. This sample was tested and identified as the novel coronavirus SARS-CoV-2—commonly referred to as COVID-19, the seventh member of the coronavirus family that infects humans. On January 20, 2020, the first confirmed case of COVID-19 was reported in the United States (US). The introduction of the virus into the US prompted the Centers for Disease Control and Prevention (CDC) and the Surgeon General to issue a recommendation to cease elective surgeries and procedures in order to reduce the spread of the virus, preserve personal protective equipment (PPE) supplies, and increase patient capacity in hospitals. On March 16, 2020 the American Dental Association (ADA) issued similar recommendations for elective dental procedure and preventative care, recommending only emergency dental services be provided. Ultimately, the decision to reduce or cease elective procedures was left up to each state.

A majority of states allowed dental hygienists to return to work during spring 2020, despite the threat of illness associated with COVID-19 infection, which persisted throughout the population at the time. The CDC developed COVID-19 dental guidelines to support the safety of providers and patients. These new guidelines altered the way dental hygiene is practiced. Suggested changes included: increasing the amount of protective equipment (PPE) worn; increasing duration of PPE wear-time; changes to the type of PPE used; limiting doffing of PPE throughout the day; patient screening questions and temperature taking; administering pre-procedural rinse; enacting ways to reduce aerosols; and reducing or discontinuing the use of the ultrasonic scaler. These changes resulted in longer workdays with fewer breaks.
In addition to the persistent threat of contracting the virus, these changes have increased stress levels in the dental hygiene occupation.\textsuperscript{11–14} The Transactional Theory of Stress and Coping postulates that stress is experienced when an individual perceives that demands exceed their personal resources to handle the demands.\textsuperscript{15,16} Personal or social resources may include time, health, and safety of self or loved ones.\textsuperscript{15,16} This theory also explains coping as a dynamic process with stages of appraisal of the perceived demands.\textsuperscript{15,16} Once an individual appraises demands as exceeding resources, the individual will implement coping strategies; if these strategies are not successful in mitigating stress the appraisal process will continue.\textsuperscript{16} The continuation of this process means the individual is still experiencing stress, or still perceives demands as exceeding resources.\textsuperscript{15,16} During the COVID-19 pandemic, dental hygienists’ demands on personal or social resources may have been exceeded. Coping strategies used to mitigate stress can be successful or unsuccessful.\textsuperscript{17–19} Successful coping strategies will aid in stress reduction, unsuccessful coping strategies will not reduce stress, may increase risk of burnout, increase occupational dissatisfaction, and negatively affect wellbeing.\textsuperscript{17–28}

Purpose of the Study

The purpose of this study was to investigate current perceptions of occupational risk and to identify how dental hygienists are coping with the stress of practicing during the COVID-19 pandemic.

Statement of the Problem

Dental health professionals (DHP) should feel protected and safe at work. However, they may be at an increased risk of contracting COVID-19 due to the nature of their work, including being in close proximity with patients during procedures.\textsuperscript{8,9,29–33} The
COVID-19 virus can be transmitted through aerosols by coughing, sneezing, and through contact transmission by touching one’s eyes or mucous membranes.\textsuperscript{8,9,34,35} The COVID-19 virus utilizes aerosol spread from an infected individual as the transmission route.\textsuperscript{8,9,34} Transmission via aerosols is concerning for dental hygienists seeing as certain routine procedures provided by the dental hygienists can create aerosols in the dental operatory.\textsuperscript{8,9,34} Dental hygienists are exposed to aerosols while preforming these routine procedures increasing their risk of contracting the virus.

During the COVID-19 pandemic, dental hygienists have found themselves practicing in an ever-changing work environment. These quick, sometimes unexpected changes may increase demands on dental hygienists, resulting in occupational stress. Also, practicing in an occupation considered high-risk for contracting a disease during a pandemic may lead to increased occupational stress. This stress can have negative effects on mental health and wellbeing. An increase in occupation stress and reduced wellbeing may lead dental hygienists to leave the profession contributing to a workforce shortage. However, if dental hygienists can be offered appropriate support to reduce occupational stress and increase wellbeing this may curb the loss of dental hygienists from the workforce.

Currently little is known about how dental hygienists are coping with the stresses of practicing during the COVID-19 pandemic. Identifying perceptions of dental hygienists practicing during the COVID-19 pandemic will contribute to a better understanding of the origins of occupational stress during a public health crisis and aid in understanding how dental hygienists are coping with that stress. This information can be
used to identify how to support dental hygienists during these stressful times and help protect the profession from attrition.

Significance of the Study

Identifying perceptions and coping strategies will aid in understanding if dental hygienists are able to mitigate stress, or if increased stress is a recurrent issue in the profession, leading to workforce attrition. This information could be used by the profession to identify whether practice changes are needed to reduce risks during a major public health event and improve dental hygiene workforce availability. Furthermore, understanding how dental hygienists are coping with the stresses of practicing during the COVID-19 pandemic will help identify successful or unsuccessful coping strategies. Successful coping strategies may be shared with the profession to promote wellbeing. Negative, unsuccessful coping strategies will signify stress is not being mitigated and the profession can use this information to assess what practice support may be needed for dental hygienists during a major public health event in the future. Additionally, the information from this study may help to identify ways to mitigate stress and burnout leading to workforce attrition.

Research Questions

1. What are Midwest U.S. dental hygienists’ perceptions of practicing during the COVID-19 pandemic?

2. How are Midwest U.S. dental hygienists coping with the stresses of practicing during the COVID-19 pandemic?
SECTION 2
REVIEW OF THE LITERATURE

A search of the literature regarding dentistry during the COVID-19 pandemic was completed in the databases Pubmed, Google Scholar, and CINAHL. The search terms used included, “dental,” “dental hygiene,” “COVID-19,” “attitudes, knowledge, perceptions,” “mental health,” “risk perception,” “health care workers,” “coping,” and “burnout”. These results were screened and excluded articles which were: not in the English language, editorials, duplicates, and not available online. Results which were included were: original research, literature reviews, and explanatory information about the virus. The last search of the literature was completed July 20, 2021 and yielded 134 resources. The article search regarding COVID-19 was limited to 2019 and 2020, as to not mistakenly include results from the severe acute respiratory syndrome (SARS) outbreak in 2003.

Mental Health Effects of COVID-19 on Dental Health Professionals

Practicing dentistry during a major public health event may increase stress and demands on personal or social resources. Demands may be emotional, mental, or physical. According to the Transactional Theory of Stress and Coping developed by Lazarus et al., when demands exceed personal or social resources, an individual will experience stress. The Transactional Theory of Stress and Coping developed by Lazarus et al. defines stress and coping as a dynamic process based on the interaction of an individual with their perceptions of an environment. This environment may be physical or psychological. The theory explains that no one situation or interaction itself is inherently stressful; it is the perception, and appraisal of the perception, that leads an individual to experience stress. Stress, in this theory, is explained as demands on resources, and these resources may be physical or
Cognitive appraisal is initiated when an individual perceives demands on resources, and the individual must decide if these demands exceed personal resources. This process is a dynamic, continuous process that may take place in a matter of seconds and multiple times a day. When an individual perceives a demand on resources, cognitive appraisal is initiated. If the individual perceives the demands as not exceeding resources, the appraisal process is complete and the individual does not experience stress. If the individual perceives demands as exceeding resources, the individual experiences stress, and secondary appraisal is necessary to identify a coping strategy. In the secondary appraisal phase a coping strategy is implemented to mitigate stress. The third appraisal stage is reappraisal. In this stage the individual evaluates the coping strategy implemented in the secondary appraisal stage to identify if it was successful at mitigating stress. If the re-appraisal phase identifies that the coping strategy as not successful in mitigating stress, the appraisal process will continue. The continuation of this process means an individual is still experiencing stress and has not identified successful ways of coping with that stress.

Stress, experienced as demands on resources, is impacting the psychological health of dental health professionals (DHP) practicing during the COVID-19 pandemic. It has been identified in the literature that DHP are just as susceptible to the psychological impact of COVID-19 as health care workers (HCW), or even frontline HCW, including psychological distress, depression, and anxiety.
Psychological distress. Psychological distress is a state of emotional suffering associated with stressors and demands that are difficult to cope with.\textsuperscript{59} Psychological distress has been positively associated with subjective overload which refers to how an individual perceives a given circumstance.\textsuperscript{14,29} An individual may or may not perceive the circumstance as a demand on personal resources. If the individual possesses adequate resources to pacify the demands, no change to the individual’s circumstance is made.\textsuperscript{14,16,29} Conversely, when an individual perceives demands as exceeding personal resources, stress is a byproduct of this interaction.\textsuperscript{15,16} Mijiritsky et al., and Shacham et al., conducted studies in China, India, Israel, Italy, and the United Kingdom and found subjective overload was positively correlated with psychological distress in DHP practicing during the COVID-19 pandemic.\textsuperscript{14,29} Increased demands, in the form of perceived risk, and perceived fear of contracting COVID-19, were positively associated with psychological distress.\textsuperscript{14,29} This is concerning for DHP as psychological distress may lead to long-term mental illness and reduce wellbeing.\textsuperscript{14,29,59}

Depression. Depression manifests as loss of engagement or interest and role impairment (i.e.-- not being able to perform daily activities such as chores, maintain a career, maintain relationships or social activities.)\textsuperscript{60–63} Depression among a sample of 4,776 dental hygienists in the United States during COVID-19 was assessed in a study using the Patient Health Questionnaire (PHQ).\textsuperscript{43} Researchers found 16% reported elevated depressive symptoms since the beginning of the COVID-19 pandemic in March 2020.\textsuperscript{43} Dental hygienists aged 18–29 years reported highest levels of depressive symptoms with the lowest levels reported among those 64 years of age and older.\textsuperscript{43}
Anxiety. Anxiety is a feeling of intense, persistent, and excessive worrying about a situation; fear can be associated with anxiety.\textsuperscript{64} Anxiety is an indicator for underlying mental illness when feelings interfere with everyday activities.\textsuperscript{64} The General Anxiety Disorder Assessment (GAD-7) assesses the severity of generalized anxiety symptoms.\textsuperscript{65,66} These symptoms include: feeling nervous or on edge, not being able to stop or control worrying, worrying excessively about a variety of things, trouble relaxing, restlessness to the point of having difficulty being still, being easily annoyed or irritable, and feelings of dread or anticipating awful or tragic events.\textsuperscript{66} This tool has been utilized to assess anxiety in DHP practicing during the COVID-19 pandemic showing an increased level of generalized anxiety symptoms in over half of the populations sampled.\textsuperscript{11,13} The GAD-2 was used in a population of 4,776 dental hygienists in the United States and found 25.7\% reported generalized anxiety symptoms.\textsuperscript{43} These studies identified positive correlations between generalized anxiety symptoms and concerns about self, family, or friends contracting the virus; correlations were also identified between generalized anxiety symptoms and concerns for the future of the dental profession.\textsuperscript{11,13,40} Higher levels of anxiety were identified in DHP who discontinued clinical practice due to the virus, as compared to those who did not discontinue practice.\textsuperscript{13,40} These results show that even though non-practicing DHP no longer experienced occupational exposure to the virus they were still suffering from increased levels of anxiety.\textsuperscript{13} The main concerns of DHP who discontinued practicing and DHP who continued to practice were similar, including, fear for the future of the profession and concern of contracting the virus; however, the non-practicing DHP additionally
reported financial stress as a concern.\textsuperscript{11,13,40,45} Research on the effects of COVID-19 on DHP has shown that anxiety, was also correlated with psychosocial concerns.\textsuperscript{11,13,40,45}

Psychosocial Effects of COVID-19 on Dental Health Professionals

Psychosocial refers to the interconnection between an individual’s thoughts and behaviors with social factors.\textsuperscript{45} Psychosocial concerns of DHP practicing during the COVID-19 pandemic can be both negative and positive.\textsuperscript{11–13,29,40–42,45,47,49} Negative psychosocial concerns include fear of infection for self or loved ones, financial stress, increased occupational stress, and fear for the future of the profession.\textsuperscript{11–13,40,41,45} Positive psychosocial effects include increased exercise, increased self-care practice, and a sense of closeness with family and loved ones.\textsuperscript{11–13,40,41,45} Isiekwe et al. surveyed a small sample of DHP about their perceived psychosocial wellbeing in relation to the COVID-19 pandemic by asking participants if they believed there would be an effect on psychosocial wellbeing, such as, feelings of depression, happiness, unhappiness, or whether it was too early to tell what the effects would be.\textsuperscript{58} Out of the 73 DHP surveyed, 38\% of the sample agreed that there would be a lasting effect on psychosocial wellbeing, but it was too early to know what that effect would be.\textsuperscript{58} Similarly, Consolo et al., Tysi\-mista et al., found that the psychosocial impact of the COVID-19 pandemic is unclear and may be negative or positive.\textsuperscript{13,67}

Concerns for the future of the profession, financial stress due to shutdowns, fear of contracting the virus, and fear of spreading the virus to loved ones are examples of negative psychosocial effects.\textsuperscript{13,40,58} Positive effects were identified as enriching relationships with family or loved ones, feeling closer to individuals one cares for and increased self-care practices.\textsuperscript{12,58} A study conducted by Fontana et al., examined a
sample of DHP, HCW, and non-HCW and found positive psychosocial effects in the lives of DHP when analyzing questions pertaining to perceived threats of COVID-19, life experiences, quality of life, and wellbeing. It was found that DHP were less likely than non-HCW to feel threatened by COVID-19. DHP ranked exercise level, caring about one another, and self-care higher since the COVID-19 pandemic than HCW, and non-HCW.

Perceived risk. Research has shown conflicting perspectives regarding the perception of occupational risk among DHPs. Dentistry is considered a high-risk profession for transmission of airborne diseases due to the nature of procedures, producing bio-aerosols, and proximity of the DHP to the patient. If a DHP is concerned about becoming infected with the virus while practicing dentistry and does not feel adequately protected, then demands have exceeded resources, this phenomenon is explained in the Transactional Theory of Stress and Coping. In the event demands exceed perceived resources, perceptions of risk will lead to stress. Research conducted with DHP practicing dentistry in Italy, India, and the Middle East during the COVID-19 pandemic identified themes of perceived dangers and high risk situations in the dental setting for DHP and patients. COVID-19 was perceived as very dangerous, meaning that DHP have low confidence in staying healthy while practicing dentistry. This heightened perception of danger could be due to DHP viewing the dental setting as higher risk for contracting the virus than any other social setting, and the profession as higher risk than other professions. In a study by Cagetti et al. the risk of practicing dentistry during the pandemic was reported to be not acceptable by 99% of 583 DHP surveyed. Viewing the risk as unacceptable may be due to the perception of
the virus being highly contagious and fatal. Kamate et al. found that 95.9% of 860 DHP reported that they perceive the COVID-19 virus as fatal in nature.72

This heightened risk is seen as a barrier to providing safe care in the dental setting because DHP see the virus as difficult to avoid while providing treatment to the patient. Further, some DHP have reported perceptions of the patient being at a higher risk than the DHP of contracting the virus during dental treatment. Alternatively, one study reported DHP perceived the patient and the DHP to have the same risk for transmission during the dental appointment, while others perceived the patient at a low risk of contracting the virus. A study in the United States with 4,667 dental hygienists found the perceived risk to self and patient safety was correlated with the amount of PPE available in the dental setting. Less risk was perceived when the dental setting had more than 14 days of PPE on hand, specifically N95/KN95 masks.

Treating patients with suspected COVID-19 symptoms was also examined in the research and showed varying levels of comfort among DHP providing care. Some DHP have reported they would decline treating patients with COVID-19 symptoms. However Arora et al. found that 41.8% of the 646 DHP surveyed would be willing to provide care for COVID-19 positive patients. Similarly, a study by Khader et al. found that 36.7% of the 368 dentists sampled did not view COVID-19 as a serious public health issue. Further, this study showed that while 32.2% of the participant dentists would allow their staff to provide treatment to patients with COVID-19 symptoms, 82.6% would personally avoid treating patients with symptoms. Current research displays the spectrum of risk perceptions among DHP.
Practicing in an environment with other DHP who have differing perceptions of risk may lead to increased occupational stress due to increased demands on an individual. Demands may be mental, physical, or emotional events an individual experiences as stressful. The feeling of having little or no support, and not being able to change a situation can increase demands on an individual, and potentially lead to stress or contribute to the perception that a situation is more stressful. Plessas et al., found DHP felt frustrated, undervalued, and vulnerable, facing emotional and physical challenges with inconsistent and changing guidelines from leadership. Shirahmadi et al. and Shacham et al. found that higher levels of self-efficacy are associated with lower levels of perceived risk of COVID-19. These results suggest the more control an individual feels they have over a situation, the less they perceive the situation as a threat or as stressful. For example, higher levels of anxiety were found in DHP who discontinued their clinical practice as compared to those who did not; suggesting DHP with potentially less control of their situation perceived more demands.

Fear of practicing during COVID-19. The perception of fear is a theme identified in the literature on practicing dentistry during the COVID-19 pandemic. Fear of being in close contact with others due to the perceived risk of transmission, becoming infected with COVID-19, transmitting the virus to loved ones, and financial ramifications have been identified in the literature. In a study of 686 DHP in India, 92.3% stated they were scared to offer treatment to a suspected COVID-19 positive patient and 77.6% were scared of cross infection from a coworker. Fear of transmitting the virus to family members or loved ones was reported as more concerning for DHP than contracting the virus themselves.
fear was reported by DHP as the main reason for declining to treat patients with COVID-19 symptoms. A study of 203 dental interns in Saudi Arabia found 80.8% were worried about contracting the virus themselves, and 85.7% reported being worried about spreading the virus to family or loved ones.

Fear of negative financial consequences has been reported by DHP for several reasons. First, DHP are concerned about the personal financial ramifications, if they or a family member or loved one becomes ill. Fontana et al., found that over 70% of the 984 participants surveyed reported concern about financial problems or impacts if a person close to them contracted COVID-19. If DHP become ill, they would be required to quarantine and therefore not be able to practice. With no income, DHP fear they will not be able to pay for medical care.

Beyond personal financial impact, DHP are also concerned with the financial impact of COVID-19 on the profession. Aravind et al., found that 99% of 686 DHP surveyed indicated they were scared of the financial ramification of the COVID-19 pandemic. In agreement with these findings Humagain et al. found 70% of 406 dentist sampled in Nepal were severely affected by the COVID-19 pandemic financially, and were not receiving an income in May of 2020. The monetary impact of the COVID-19 pandemic may include consequences from reduced clinic income and increased costs associated with infection control measures. Governmental orders to halt elective procedures, voluntary dental office closures to limit the spread or due to infections, limited patient interactions due to low PPE supplies, increased time between appointment, and reducing bioaerosol producing procedures have all contributed to monetary ramifications. Adding to this financial stress is the concern
patients may not feel safe in the dental setting due to the fear of contracting the virus. A study by Aquilant et al., in a population of 1003 members of the public in Italy, found 22.6% would attend a dental apportionment but be fearful for their health, and 18.3% would either postpone or cancel their appointment. Another concern is patients may not be able to afford dental care due to increased job loss and the financial slump caused by the COVID-19 pandemic, keeping patients away from the dental office leading to lost revenue. This increased perception of risk from the patients may lead to more financial concerns for DHP, causing more stress. The COVID-19 pandemic has had a negative impact on DHP psychological state, calling for a greater understanding of coping strategies that may be used to increase wellbeing.

Coping Strategies Among Health Care Workers

Coping strategy research involves identifying how individuals are currently dealing with stressors and identifying those strategies as adaptive or maladaptive. The goal is to ultimately offer support or education to change maladaptive strategies, thereby reducing negative effects of occupational stress and promoting or increasing wellbeing. Literature has pointed to the importance of HCW wellbeing and improved work-life balance as a major need. This research highlights the Quadruple Aim of Healthcare: to enhance patient experience, improve population health, reduce costs, and improve the work life of health care providers. When a HCW is suffering from stress due to maladaptive coping strategies, it may reduce the quality of care the HCW is providing resulting in reduced patient satisfaction, increased costs, and poor health outcomes. Therefore,
identifying negative or maladaptive coping strategies may promote satisfactory patient care, increase HCW wellbeing, and reduce occupational stress and potential for burnout. Concerns for wellbeing and changing the aim of healthcare to include considerations for providers is also relevant to dentistry and DHPs.

Coping strategies include cognitive, emotional, or behavioral strategies utilized to deal with a problem or perceived stress. Coping strategies may be adaptive useful strategies, or maladaptive not useful strategies. Positive coping strategies may include cognitive strategies, such as positive refocusing or putting things into a different more positive perspective; emotional strategies, such as talking or therapy sessions; or behavioral coping, including any activity that may aid in relaxation (i.e., reading a book or going for a walk). Other positive coping strategies include behaviors to improve and support mental health, such as sleep hygiene, physical activity, and social support. Negative coping strategies may include unhealthy relationships with food or substances, or misuse of social media, both causing increased psychological distress. Negative or maladaptive coping strategies that do not aid in mitigating occupational stress will lead the individual to continually experience stress, which may eventually lead to burnout.

**Problem-focused vs. emotion-focused coping strategies.** Individual coping strategies may be problem-focused or emotion-focused. Both problem-focused and emotion-focused coping strategies can be used in positive or negative ways. These mechanisms are combined with cognitive, behavioral, or emotional strategies. Problem-focused coping is a mechanism that focuses on changing or resolving a stressful situation or modifying the source of the stressful stimuli. Emotion-focused coping is a form of
coping that involves managing emotions of the individual, not altering the situation causing the stressful stimuli. A meta-analysis of 36 studies involving 9,729 HCW, teachers, social workers, counselors, clergy, parents of children with autism, tradesman, and civil servants identified a negative correlation between problem-focused coping and occupational burnout, and a positive correlation between emotion-focused coping and occupational burnout.

Problem-focused coping strategies have been identified as beneficial to HCW coping. These coping strategies included positive refocusing, planful problem solving, positive self-attitude, and positive outlooks on the situation. Another form of problem-focused coping was identified in the form of information gathering. It was identified that the more information HCW had about the COVID-19 virus the more confident they felt in avoiding transmission and the more prepared they felt in avoiding contraction. Education found to be helpful included information about the transmission, containment, and personal protective measures to avoid transmission. A study by Wang et al., showed a correlation between formal informational lessons about the virus and confidence in coping with its effects.

Emotion-focused coping strategies include denial, avoidance, or distraction. These mechanisms are seen to be used in situations that are perceived as uncontrollable. They have not been identified as beneficial to HCW coping and are not found to be frequently utilized by HCW. However one study did find HCW under the age of 40 used avoidance coping strategies more than the population over 40 years of age.
**Social support.** Research has identified common coping strategies utilized by HCW during the COVID-19 pandemic. The most common trend identified was seeking emotional and social support from friends and family members. This type of support came in the form of talking with friends or family members or reaching out to social platforms for emotional and social support. However, HCW surveyed during the COVID-19 pandemic, did not seek coworker support or support during team meetings as a coping strategy. A study by Windarwati et al. found 98.7% of 236 HCW surveyed reported seeking support from friends and family. Salopek-Žiha et al. found that age plays a role in the use of social support as a coping strategy in a sample of HCW. In this study, the population over 40 years of age used more social support, while the population under 40 years of age was more likely to avoid social support. The author pointed out this was due to the younger population wishing the pandemic never happened and fantasizing it would simply go away, while the older population accepted the circumstance and reached out to others discuss their feelings.

**Coping Strategies Among Dental Health Professionals**

Coping with the stress of practicing during the COVID-19 pandemic has been examined in HCW however very a few studies are available for DHP. Occupational coping strategies utilized by DHP, outside of a major public health event, have been identified as physical activity or exercise, support from loved ones, self-care, quiet time, and time with family and loved ones. Prior to the COVID-19 pandemic, problem-focused and emotion-focused coping strategies have been identified in DHP outside of a major health event, with emotion-focused coping strategies shown to
be maladaptive and not successful in mitigating stress.\textsuperscript{22,23,28,41} Maladaptive coping strategies and risk perceptions contribute to clinician burnout and reduced wellbeing, which may lead to a workforce shortage in the dental hygiene profession.\textsuperscript{19–21,24–27,44,103,104,107,108,119,124,126–131}

**Deep acting and surface acting coping.** Research on coping identifies emotional demands as the most common occupational stressor and more taxing on DHP than the overarching stress of clinical practice.\textsuperscript{22,23,28,124} Sander et al. used the terms deep-acting and surface-acting to explain how DHP adapted personal emotions to deal with the emotional demands of their occupation.\textsuperscript{124} These terms share similar definitions to problem-focused coping and emotion-focused coping.\textsuperscript{18,106,124}

Deep-acting, similar to problem-focused coping, is how an individual changes their perspective on a situation to mitigate stress.\textsuperscript{18,106,124} This is referred to as deep-acting because the individual actually changes how they perceive or understand a situation and their outlook on the given situation is revised.\textsuperscript{124,132} Deep-acting has been shown to aid in mitigating occupational stress and is not correlated with the feeling of emotional exhaustion.\textsuperscript{124} Individuals utilizing deep-acting may be at less risk for occupational burnout since emotional exhaustion is a precursor to burnout.\textsuperscript{20,24,119,120,124} Surface-acting, similar to emotion-focused coping, is how an individual modifies outward expressions but does not change inner thoughts or views of the situation.\textsuperscript{132,124} Surface-acting is positively associated with the feeling of emotional exhaustion.\textsuperscript{124} Therefore, individual utilizing surface-acting may be at an increased risk for occupational burnout.\textsuperscript{20,24,119,120,124} Chapman et al. pointed out that emotional arousal has adverse
effects on DHP clinical practice and decision-making, leading to a negative impact on patient care.\textsuperscript{22,23,28}

Research on coping strategies used while practicing during the COVID-19 pandemic is limited. Pleassas et al. looked at a sample of 38 dentists and dental nurses in the United Kingdom and identified team meetings, co-worker support, monitoring mental health and wellbeing, taking breaks, not working overtime, spending time outdoors, meditation and coloring were found to be successful coping strategies.\textsuperscript{85} A literature review by Bastani et al. found common infection control coping strategies in dental offices included implementing patient screening tools, increased infection control and utilizing virtual or tele-dentistry.\textsuperscript{133}

Exploring how DHP are currently dealing with stressors, identifying adaptive and maladaptive coping strategies, may lead to the identification of strategies that support adaptive coping or education to change maladaptive coping strategies with the goal of reducing negative effects of occupational stress and promote wellbeing during pandemics or other disruptive events.\textsuperscript{17,19,25–27,44,103–106} DHP who are able to identify emotions and implement coping strategies could increase psychological resilience, wellbeing, and decision-making skills to sustain dental care practices during a major public health crisis and contribute to achieving the Quadruple Aim in dentistry.\textsuperscript{22,23,28}

Therefore, the purpose of this study was to identify current perceptions and coping strategies utilized by dental hygienists in five US Midwest states including, Iowa, Minnesota, North Dakota, South Dakota, and Wisconsin, during a major public health crisis, such as a pandemic. This will aid in a better understanding of how these events effect dental hygienists personally, and how dental hygienists are dealing with the effects.
This information can be used by the profession to identify what support may be needed to reduced workforce attrition and betterment of the profession.
SECTION 3
MANUSCRIPT
This manuscript will be submitted to the Journal of Dental Hygiene.

Introduction and Literature Review

On December 30, 2019, in Wuhan City, Hubei province, China, the novel coronavirus—commonly referred to as COVID-19, was detected.\textsuperscript{1–3} The introduction of the virus into the United States (US) prompted the Centers for Disease Control and Prevention (CDC) and the Surgeon General to issue a recommendation to cease elective surgeries and procedures in order to reduce the spread of the virus, preserve personal protective equipment (PPE) supplies, and increase patient capacity in hospitals.\textsuperscript{5,6} On March 16, 2020 the American Dental Association (ADA) issued similar recommendations for elective dental procedure and preventative care, recommending only emergency dental services be provided.\textsuperscript{7}

The CDC developed COVID-19 dental guidelines to support the safety of providers and patients.\textsuperscript{5} Suggested changes included: increasing the amount of protective equipment (PPE) worn; increased duration of PPE wear-time; changes to the type of PPE used; limiting doffing of PPE throughout the day; patient screening questions and temperature; administering pre-procedural rinse; enacting ways to reduce aerosols; and reducing or discontinuing the use of the ultrasonic scaler.\textsuperscript{5,8,9} These changes result in longer workdays with fewer break, warmer working conditions, decreased visibility, compromised ergonomics and musculoskeletal stress.\textsuperscript{5,10}

Dental health professionals (DHP) are at an increased risk of contracting COVID-19 due to the nature of work, including being in close proximity with patients during procedures.\textsuperscript{8,9,29–33} Research has shown that COVID-19 can be transmitted by coughing, sneezing, and through contact transmission by touching one’s eyes or mucous
membranes. DHP are in high contact with these areas, increasing the risk of transmission. Practicing in an occupation considered high-risk for contracting a disease during a pandemic may lead to increased risk/risk perceptions and stress.

Occupational burnout and reduced wellbeing have also been linked to increased costs, reduced health outcomes, reduced patient satisfaction, and increased employee turnover. It has been identified in a study with 4,776 dental hygienists in the US that the dental hygiene workforce has seen an 8% reduction since the start of the COVID-19 pandemic, March 1, 2020, with participants in this study citing concerns about COVID-19 as the reason for employment reduction.

Research has identified increased stress on DHP practicing during the COVID-19 pandemic due to recommended practice changes and the persistent threat of contracting the virus while practicing. Stress of contracting the virus while practicing is heightened due to the nature of the virus as it is transmitted via aerosols, which are commonly created during many routine dental procedures. This stress has shown to have a negative effect on mental health in the forms of anxiety, depression, and psychological distress. The literature shows that DHP are just as susceptible to the psychological impact of COVID-19 as health care workers (HCW) including frontline HCW. Studies from China, India, Israel, Italy, United Kingdom, and the US have identified that more research is needed to establish proper mental health support systems for DHP practicing during major public health events to decrease perceived demands and the subsequent effects on mental health.

Further, how DHP perceive the risks of practicing during a pandemic can also affect the amount of stress experienced. Increased risk perceptions may signal
increased demands on DHP resources once again leading to stress, reduced wellbeing and potential for burnout. Practicing in an environment with other DHP who have differing perceptions of risk may lead to increased occupational stress due to an increase in perceived demands.

The Transactional Theory of Stress and Coping postulates that stress is experienced when an individual perceives demands exceed personal resources available to handle the demands. Demands may include anything requiring more attention or effort from an individual; demands may be physical, emotional, social, or mental. Personal resources may include thing such as time, finances, health, safety of self or loved ones. Once an individual perceives demands as exceeding resources, the individual will implement coping strategies; if these strategies are not successful in mitigating stress the stress response continues. The continuation of this process means the individual is still experiencing stress, or still perceives demands as exceeding resources.

Coping strategies utilized to mitigate stress can be adaptive (successful) or maladaptive (unsuccessful). Adaptive coping strategies will aid in stress reduction, maladaptive coping strategies will not reduce stress, may increase risk of burnout, increase occupational dissatisfaction, and negatively affect wellbeing. Currently there is no research identifying how DHP are personally coping with the stresses of practicing during the COVID-19 pandemic.

The aim of this descriptive cross-sectional study is to identify perceptions and coping strategies of dental hygienists’ in five US Midwest states including Minnesota.
(MN) and the surrounding states, Iowa (IA), North Dakota (ND), South Dakota (SD), and Wisconsin (WI), since the start of the COVID-19 pandemic, March 1, 2020.

Methods and Materials

A descriptive cross-sectional survey design was used for this research. This study was conducted by a student investigator and overseen by a primary investigator at the University of Minnesota (UMN) School of Dentistry (SOD). The UMN Institutional Review Board (IRB) deemed this study (STUDY00012814) exempt from oversight due to the nature of the research involving a survey and posing minimal risk to participants.

Informed consent was achieved with an electronic consent form in Qualtrics\textsuperscript{XM}, a secure web-based tool.\textsuperscript{136} The voluntary nature of the research was explained in an email which contained a link to the consent form and survey. The survey was not accessible without completing the consent form. The initial email was sent July 2021, and bi-weekly remaindered were sent to non-responders for a total of six weeks. The survey closed to all participants August 2021. Responses were confidential, de-identified and only aggregate data was reported. Only investigators and the statistician had access to the aggregate data. Data integrity was maintained using the UMN Box secure storage.\textsuperscript{137} Examiner calibration was not required due to electronic administration.

Participants

Participants included dental hygienists in MN and the surrounding states – IA, ND, SD, and WI. A convenience sample of the dental hygienists was collected by purchasing email addresses of licensed dental hygienists from Complete Medical Lists, a company that provides this information for marketing and research purposes.\textsuperscript{138} There was a total of 3,868 email addresses to purchase from Complete Medical Lists for the five
A power analysis determined sample size was deemed unnecessary due to descriptive research with no hypothesis testing. Inclusion criteria includes licensed dental hygienists practicing dental hygiene on March 1, 2020, or any amount of time during the COVID-19 pandemic. Exclusion criteria includes individuals who are under the age of 18 and who do not hold a dental hygiene license. Participants self-identified as dental hygienists practicing on March 1, 2020 or during any time thenceforth.

Instrument

This instrument was developed by the investigator and was based on the theoretical framework used for this study. The three sections of this instrument were initially piloted tested among fifteen practicing dental hygienists and then modified for comprehension, accuracy, and readability. A second round of pilot testing with eight practicing dental hygienists was completed. Pilot testing of the instrument provided face validity.

The instrument included three sections: demographics, employment, and perceptions/coping strategies. Demographic data included: age, gender, marital status, ethnicity, state, years practicing, practice type, number of coworkers, COVID-19 diagnosis for family/coworkers/patient, and vaccination status. Employment questions included yes/no and open response questions aimed at past and current employment statutes, contributions to changes in employment status. Perception and coping strategies were measured with 38 statements on a 5-point Likert-type scale, 1 = strongly disagree and 5 = strongly agree. Qualitative data was collected with four open questions: “What factors contributed to your decision to leave the profession?”; “What factors will influence your decision to return to the profession?”; “What other factors contributed to
your decision to reduce your working hours?” These questions were only asked of participants who answered yes to either leaving the profession or reducing hours. The last open question, “If you have engaged in practices to improve your mental health during the COVID-19 pandemic please explain these practices”, was posed to all participants.

A deductive approach to thematic analysis was used, based on the transactional theory of stress and coping. Themes for the first three qualitative questions were developed to encapsulate all forms of demands participants may experience on personal resources.

Statistical Analysis

Survey respondent demographics were summarized as means and standard deviations or frequencies and percentages for continuous and categorical characteristics respectively. For quantitative analysis, bivariate comparisons between respondent demographics and survey responses regarding perceptions and coping strategies were computed using a Fisher’s Exact test. Survey responses were both analyzed as the original 5-point Likert scale and a collapsed 3-point Likert scale assessing overall agreement, disagreement, and neither agreement nor disagreement. Qualitative analysis was conducted using inductive analysis to code responses to four open response questions and codes were used to develop themes. All statistical analyses were conducted at the 0.05 significance level using the R statistical software (version 4.1.0).

Results

Of the 3,868 surveys emailed 45 were incomplete, 51 undeliverable, and 167 completed to comprise the final sample with a 4.4% response rate.

The majority of respondents were female, white, age 56 or over, employed full time, and had been in practice for ≥ 21 years (Table 1). Since March 1, 2020, 7.2% of
respondents reported leaving the profession, with the majority citing COVID-19 associated reasons (58.3%, n = 7) with no plans to return (83.3%, n = 10). Reduction in working hours was reported by 8.4% (n = 13) of participants with the majority (61.5%, n = 8) citing risk associated with practicing during the COVID-19 pandemic as the reason for the reduction (Table 2).

Table 3 summarizes participants' perceptions of practicing during the COVID-19 pandemic. The majority of dental hygienists perceived their risk of contracting the COVID-19 virus was increased while practicing (62.3%, n = 104), that practicing during the COVID-19 pandemic was seen as a threat to the health of family and/or loved ones (49.1%, n = 82), and practicing now was more physically demanding than before the pandemic (70.6%, n = 118). The COVID-19 vaccine was perceived as reducing the risk while practicing (58.7%, n = 98).

Coping strategies used during the COVID-19 pandemic are summarized in Table 4. Dental hygienists are coping with the stresses of practicing during the COVID-19 pandemic by engaging in practices to improve mental health (42.5%, n = 71), turning to personal relationships (79.1%, n = 132), exercising (43.1%, n = 72), focusing on spirituality (34.2%, n = 57), and increased social media use (44.3%, n = 74). Participants also found themselves becoming more agitated (40.1%, n = 67), and worrying more (46.7%, n = 78), since the start of the pandemic. Other coping strategies used infrequently can be found in Table 4.

Correlations

Correlations were identified between the age of participants and two coping strategies, and years of practice with two coping strategies (Table 5). Table 6 displays the
correlations between stress, risk perceptions, and coping strategies for individuals who considered leaving or left the profession due to stress. Stress and risk of practicing during the COVID-19 pandemic were positively correlated with participants who either left (p = 0.001) or considered leaving (p = <0.001) the profession (Table 6). In the population who left the profession due to stress (41.6%, n = 7), a correlation between stress and worrying was identified (p = 0.034). The population who considered leaving the profession due to stress (36.1%, n = 56) was correlated with greater perceptions of risk. Coping strategies used by this group included engaging in practices to improve mental health (p = 0.05), finding comfort in alcohol (p = 0.004), spending more money on non-essential goods and services (p = 0.004), becoming more easily agitated (p = <0.001), experiencing changes in sleep patterns (p = <0.001), and worrying (p = <0.001).

Qualitative

Eight themes emerged including Physical and Personal Health Concerns, Retirement, Employer Reduced Hours, Vaccination, Education, PPE, Physical Demand, and Family. The last question pertained to coping strategies, these themes were identified based on likeness. Themes included Physical Activity, Wellness Activity, Religion, Personal Relationships, Education, and Mental Health Management. Themes were identified by reviewing all responses and then grouping common responses within each category. Qualitative data from the open questions is summarized in Tables 7-9.

Discussion

The purpose of this study was to identify dental hygienists’ perceptions of practicing during the COVID-19 pandemic, March 1, 2020 to August 14, 2021, and identify coping strategies utilized during this time. This research identified dental
hygienists perceived practicing dental hygiene during the COVID-19 pandemic put them, their families and/or loved ones at more risk of contracting the virus. Further, participants reported practicing dental hygiene was more physically demanding now than before the start of the COVID-19 pandemic. However, the majority of participants felt adequately supported with PPE, education, and employer support. The COVID-19 helped dental hygienists feel they were at less risk while practicing dental hygiene.

Employment

Regarding employment finding in this study, few of the respondents, 7.2% (n=12), reported leaving the profession. However, 8.4% (n=13) reported reduced hours of employment. Reasons for reduced employment were cited as COVID-19 risk, stress, physical demands, concerns about PPE/safety, and employer-reduced hours. These findings are similar to a recent study examining 4,776 dental hygienists’ employment status and found 7.9% reported leaving the profession since March 1, 2020 and 6.7% shifted from full to part time.\textsuperscript{83} In that study, childcare was a reason cited for leaving the profession.\textsuperscript{83} In the current study, that trend was not specifically identified, however family obligations were cited as a reason for reduced hours by 30.8% (n=4) of the dental hygienists who reported reduced hours. The trend of shrinking employment numbers is not exclusive to dental hygiene. A study by Bhandari et al., found a 19% increase in unemployment in dentists from March to April 2020 in the US.\textsuperscript{140} This trend is similar in physician and nursing staff but at lower rates, 1.4% and 4% respectively.\textsuperscript{140} In agreement with these findings, this study identified one quarter of respondents reported they were considering a different profession than dental hygiene. It is worth noting that current research on the profession of dental hygiene found job satisfaction and burnout to be
correlated with the intention to leave the profession.\textsuperscript{141} The perception of increased risk may contribute to a reduction in job satisfaction and increase risk for burnout. Personal burnout and work-related burnout have been correlated, showing that occupational or even non-occupational perceptions may contribute to reduced job satisfaction and have effects on the workforce.\textsuperscript{142} These results signify a potential for increased workforce attrition due to the strain of the COVID-19 pandemic. This could become a roadblock for patients seeking care, and dental offices seeking employees. The US Bureau of Labor Statistics (BLS) reported the profession of dental hygiene is projected to grow by 11\% between 2020 and 2030.\textsuperscript{143} This growth rate is higher than the average occupational growth rate of 8\%.\textsuperscript{143} BLS also noted dental hygiene job openings in the US are projected to rise from 15,600 to 23,100 by 2030.\textsuperscript{143}

Perceptions

Dental hygienists’ perceptions while practicing during the COVID-19 pandemic were identified as a heightened level of perceived risk and a perceived threat to the health of self and family/loved ones while practicing dental hygiene. Similarly, other studies have found DHPs perceived the dental setting as high-risk for contracting the SARS CoV-2 virus and a risk to their personal health.\textsuperscript{42,72,144,145} In a study by De Stefani et al., dentists perceived the virus as very dangerous and were not confident in being able to work safely.\textsuperscript{41} Shenoy et al., found DHPs were scared of becoming infected with the COVID-19 virus from a patient or co-worker and anxious about a possible infection, even with appropriate PPE.\textsuperscript{144} Similarly, the participants in this study perceived practicing as a risk and threat to health, even with the majority reporting they have sufficient PPE.\textsuperscript{144} This is contrast to Estrich et al., who found appropriate/adequate PPE to be correlated
with less concern about contracting the virus. Other studies found DHPs reported stress about returning to work due to the risk of infection; perceived COVID-19 in the dental setting as very threatening; and perceived practicing dentistry as high risk for infection more than any other activity. Conversely, the majority of participants in the current study did not agree practicing dental hygiene was riskier than any other activity.

The current study identified 83.8% (n=140) of respondents felt safe with the type of PPE provided and 83.2% (n=139) felt they had an adequate PPE supplied to them. However, feeling adequately protected from the virus while practicing may not be linked to PPE exclusively. In this study the COVID-19 vaccine did help dental hygienists feel they were at less risk while practicing 58.7% (= 98). Likewise, a recent study found the vaccine aided in the reduction of fear and anxiety in dental professionals and led to a reduction in PPE usage. This suggests a combination of vaccination and appropriate PPE may be needed to reduce the feeling of risk.

A survey of 368 dentists by Khade et al., during the COVID-19 pandemic found 43.8% would not treat patients with flu-like symptoms, but 32.3% would allow their staff to treat these patients. Allowing staff to work with potentially infectious patient during a pandemic may increase stress. In contrast to these findings the majority of dental hygienists in our study indicated they felt supported by their employers in the form of good communication from the employer during shutdowns or closures, feeling the employer valued safety and provided appropriate/adequate PPE.

Coping

Addressing the second aim of this study involves understanding dental hygienists coping strategies. Dental hygienists reported a variety of adaptive (positive) and
maladaptive (negative) coping strategies used to mitigate stress during the COVID-19 pandemic. Adaptive coping strategies, mitigate stress, and included engaging in practices that improved mental health, finding support in personal relationships, focusing on personal health in the form of diet, exercise, and spiritual practices. Maladaptive coping strategies do not mitigate stress, and included avoiding social interactions, finding comfort in food, alcohol, or tobacco to deal with stress, spending more money on non-essential goods and services, becoming more easily agitated, changes in sleep patterns, and increased worry.

The Transactional Theory of Stress and Coping identifies stress and coping as an imbalance between an individual’s perceived demands and resources. Demands can be anything an individual values such as health, safety, or time. This research found dental hygienists perceived themselves and their families and/or loved ones as at risk while practicing during the COVID-19 pandemic. The perception of risk may be a demand that exceeds an individual’s resources, leading to stress in this population. Further, they reported dental hygiene practice as more physically demanding now than before the pandemic. Work that is perceived as more physically demanding may also lead to stress. Dental hygienists may not have the proper support to deal with this stress, which may have contributed to the increased agitation and worry reported by most participants. These maladaptive coping strategies do not mitigate stress. Utilizing coping strategies that do not mitigate stress will lead an individual to continually experience stress. Prolonged stress may lead to reduced wellbeing or even burnout. Unmitigated, prolonged stress, in combination with increased physical
demands while practicing dental hygiene, as reported by the majority of participants, could contribute to dental hygiene workforce attrition.

The majority of participants reported increased social media use since the start of the COVID-19 pandemic. Increased social media use can be considered either an adaptive or maladaptive coping strategy, depending on the context and content of the use. Increased social media used to connect with friends and/or loved ones may offer social support. Additionally, social media can be used to disseminate important formation to professional groups, quickly enhancing understanding and adoption of protective measures. Conversely, higher prevalence of mental health problems have been associated with frequent social media exposures during the COVID-19 pandemic. Frequently viewing disturbing images or reading sensationalized articles may lead an individual to feel they are more at risk of contracting the virus, leading to more stress. However, the current study did not specify what content the participants were accessing using social media. Understanding how social media is used by dental hygienists during a public health crisis is important to promoting mental health and wellbeing for workforce retention.

Participants in this study noted using personal relationships to provide support, engaging in practices to improve mental health, and focusing on health in the form of exercise and spirituality as useful coping strategies to mitigate stress. Supporting adaptive coping strategies may help increase wellbeing, reduce stress, and reduce workforce attrition during a public health crisis. The profession could aid in supporting and facilitating these strategies through education and resources geared toward dental hygienists or employers.
A focus on practitioner wellbeing is critical to sustain the dental hygiene workforce during a major public health crisis. The Quadruple Aim of Health Care focuses on practitioner wellbeing as well as improving the experience of care, improving the health of populations, and reducing per capita costs of health care. Striving for the Quadruple Aim in the dental hygiene profession will increase practitioner wellbeing and protect the profession from a potential workforce shortage due to the emotional, mental, and physical demands of practicing during the COVID-19 pandemic. Consideration for the patient when discussing the Quadruple Aim is also a key component. A reduction in the dental hygiene workforce will leave patients without care. It is important to note that practitioner wellbeing has been linked to improved patient outcomes and reduced clinical errors. Ultimately the practitioner and patient will benefit from striving for this aim. However, more research on coping strategies and improved wellbeing is necessary to achieve the Quadruple Aim in dental hygiene.

Limitations

Limitations include a low response rate, recall bias, and self-reporting bias leading to a social desirability bias. A low response rate may be due to the timing of the survey, sent in the middle to late summer of 2021. Participant may have used the summer to recover from children’s ever changing learning environment, online to hybrid models. Some potential participants could have used the summer to reduce their connectivity and missed the email. Despite the low response rate, no study has explored perceptions and personal coping strategies of dental hygienists during a pandemic. This study will serve as preliminary evidence for future research.

Future Research
Future research should explore ways to reduce risk perceptions and support coping strategies to reduce stress for dental hygienists practicing during major public health events to improve provider wellbeing and avoid a dental hygiene workforce shortage. Current research on practicing amid the COVID-19 pandemic is largely focused on dentists’ knowledge, perceptions, and experiences. The role dentists and dental hygienists play in the practice setting are different and more research on the experiences of dental hygienists during this time will offer more insight into the support needed by the profession.

Conclusion

Dental hygienists perceive practicing dental hygiene during the COVID-19 pandemic as putting themselves at risk of contracting the COVID-19 virus and a hazard to their health and the health of their families and/or loved ones. The practice of dental hygiene is more physically demanding than before the COVID-19 pandemic and dental hygienists are more agitated and worried. Dental hygienists are finding ways of coping with these stresses by engaging in practice to improve mental health, using personal relationships for support, exercising, turning to spirituality, and using social media more than before the pandemic. Dental hygienists in this study reported reduced hours of work or leaving the profession, contributing to workforce attrition. The results from this study can be used to understand perceptions of dental hygienists and support successful coping strategies to mitigate stress while practicing during a public health crisis.

SECTION 6
Appendix A: Practical Application

Dental hygienists are at an increased risk of contracting COVID-19 due to the nature of their work, including being in close proximity with patients during procedures.8,9,29–35 Practicing in a profession considered high risk for contracting a virus during a pandemic may increase occupational stress on the individual.15,16

Understanding how dental hygienists perceive their clinical environment may help better understand where stress is originating during a public health crisis. Enacting policies to reduce perceived risk may aid in increased wellbeing and practitioner satisfaction. Furthermore, understanding how dental hygienists are coping with the stress of practicing during a major public health event allows the profession to identify whether stress is fully mitigated and to identify successful coping strategies. The use of maladaptive coping strategies signals stress is not mitigated and the appraisal process, as explained by Lazaurus et al., continues.15,16 Adaptive coping strategies, successful in mitigation stress, can be shared with the profession and promoted as strategies to increase wellbeing during trying time. Striving to increase practitioner wellbeing is also in alignment with the Quadruple Aim of healthcare.21 This aim includes considerations for healthcare providers’ mental and physical wellness among the other three aims.21 Fostering provider wellbeing is also in the best interest of the patient. Poor patient outcomes and increased clinical errors have been correlated with provider burnout and reduced wellbeing.153

Dental hygienists who are not successfully coping with occupational stress, or who perceive the profession as hazardous, could be offered adaptive coping strategies or risk perception alterations may be recommended. Addressing new challenges that
accompany practicing dental hygiene during a public health crisis will aid in supporting
the dental hygiene workforce and avoid a workforce shortage.
EXEMPTION DETERMINATION

Driven to Discover*
The IRB determined that this study meets the criteria for exemption from IRB review. To arrive at this determination, the IRB used "WORKSHEET: Exemption (HRP-312)". If you have any questions about this determination, please review that Worksheet in the HRPP Toolkit Library and contact the IRB office if needed.

This study met the following category(ies) for exemption:

- Research that only includes interactions involving educational tests (cognitive, diagnostic, aptitude, achievement), survey procedures, interview procedures, or observation of public behavior (including visual or auditory recording) if at least one of the following criteria is met: (i) Any disclosure of the human subjects' responses outside the research would not reasonably place the subjects at risk of criminal or civil liability or be damaging to the subjects' financial standing, employability, educational advancement, or reputation.

Ongoing IRB review and approval for this study is not required; however, this determination applies only to the activities described in the IRB submission and does not apply should any changes be made. If changes are made and there are questions about whether these activities impact the exempt determination, please submit a Modification to the IRB for a determination.

In conducting this study, you are required to follow the requirements listed in the Investigator Manual (HRP-105), which can be found by navigating to the HRPP Toolkit Library on the IRB website.

For grant certification purposes, you will need these dates and the Assurance of Compliance number which is FWA00000312 (Fairview Health Systems Research FWA00000325, Gillette Children's Specialty Healthcare FWA00004003).

Sincerely,

Clinton Dietrich, MA, CIP
Senior IRB Analyst

We strive to provide clear, consistent, and timely service to maintain a culture of respect, beneficence, and justice in research. Complete a brief survey about your experience.

IMPORTANT: All human research conducted at the University of Minnesota must adhere to the IRB guidance and requirements, Office of the Vice President for Research guidance, and the Medical School/Office of Academic Clinical Affairs guidance.
**Implementation Plan** in response to the COVID-19 pandemic. Non-medical school investigators should contact their Associate Dean for Research for information on the "sunrise" process.

Even with IRB approval, in-person research visits may not take place without documented approval by either the Medical School/OACA sunrise process or the Associate Dean for Research sunrise process. These reviews are intended to protect the health of all research participants and the broader University/Fairview communities during the COVID-19 pandemic. Researchers must inform the IRB of their approved sunrise plans. The IRB will document the approval status on ETHOS via a comment in the study history section. Please note that IRB approved COVID-19 related research is exempt from the sunrise requirements.

All researchers should review the guidance for the IRB, the medical school and their own departments as guidance is updated frequently.

Recruitment letter

Subject: COVID-19, what has it changed for Dental Hygienists in the Midwest United States?

Hello fellow Dental Hygienist,

My name is Shelah Christensen, I am a student in the Master of Science in Dental Hygiene program at the University of Minnesota.

I am conducting research about COVID-19 and the effects it has had on the Dental Hygiene community.

This research will aid in identifying Dental Hygienists’ risk perceptions and coping strategies from March 1, 2020 till now. This information will aid the profession in identifying if more resources such as education, mental health support, or practice changes are needed for Dental Hygienists during major public health events like COVID-19. This research will also aid in identifying employment trends related to COVID-19.

This survey is estimated to take 15 minutes.

All participation is voluntary and anonymous.

Your response will be greatly appreciated!

If you cannot complete this survey today it will be available until Saturday August 14th, 2021 and will close at midnight.

Follow this link to the Survey:
${l://SurveyLink?d=Take the Survey}

Or copy and paste the URL below into your internet browser:
${l://SurveyURL}

Thank you so much for your time and consideration to participate, it is greatly appreciated!

Shelah Christensen, RDH
E-mail: econo017@umn.edu

Investigator Name: Cyndee Snell
Investigator Departmental Affiliation: Department of Primary Dental Care
Phone Number: 612-626-3412
Email Address: snl0045@umn.edu
Student Investigator Name: Shelah Christensen
Phone Number: 605-212-4744
Email Address: econ017@umn.edu

Supported By: This research is supported by the University of Minnesota, Department of Primary Dental Care

Key Information About This Research Study
The following is a short summary to help you decide whether or not to be a part of this research study. More detailed information is listed later on in this form.
The goal of this study is to identify dental hygienists' perception of risk, behavior changes or coping strategies used during the COVID-19 pandemic, from March 1, 2020 till now. Getting a better understanding of these perceptions, behaviors, and strategies will aid the profession in identifying if more resources such as education, mental health support, or practice changes are needed for dental hygienists during major public health events like COVID-19. This research will also aid in identifying employment trends related to COVID-19.

What is research?
The goal of research is to learn new things in order to help people in the future. Investigators learn things by following the same plan with a number of participants, so they do not usually make changes to the plan for individual research participants. You, as an individual, may or may not be helped by volunteering for a research study.

Why am I being invited to take part in this research study?
We are asking you to take part in this research study because you have been identified as a licensed dental hygienist in the Midwest United States. This research is asking dental hygienists in the Midwest United States questions about their experiences during the COVID-19 pandemic.

What should I know about a research study?
- Whether or not you take part is up to you.
- You can choose not to take part.
- You agree to take part and later change your mind.
- Your decision will not be held against you.
- You can ask all the questions you want before you decide.
- Your answers will not be linked to your name.
- There will be no way to identify you from the answers you give.
- The survey will be available to answer for six weeks only.

Why is this research being done?
The aim of this research is to find out how dental hygienists understand and experience the risks of practicing during a major public health crisis like COVID-19, and to find out what coping strategies helped dental hygienists deal with the stress of working during COVID-19. Dental hygienists are working in new and changing environments since the start of COVID-19. They are required to wear more PPE, perform more infection control measures, and in some cases not use the ultrasonic scaler. This can lead dental hygienists to feeling more stressed and tired during the workday.

This research can help the profession identify if more support should be provided to dental hygienists during a major public health crisis, if practice changes are needed, and how an event like COVID-19 has affected employment.

How long will the research last?
We expect the electronic survey to take approximately 15 minutes to answer.

What will I need to do to participate?
You will be asked to complete an online survey by answering multiple choice and scale response questions.
More detailed information about the study procedures can be found under “What happens if I say yes, I want to be in this research?”

Is there any way that being in this study could be bad for me?
There are no risks to participating in this study; all responses are anonymous and private.

Will being in this study help me in any way?
There are no benefits to you from taking part in this research. We cannot promise any benefits to others from your part in this research.

Detailed Information About This Research Study
The following is more detailed information about this study in addition to the information listed above.

How many people will be studied?
3,867 dental hygienists were invited to participate in this study. Participation is voluntary so the exact number of dental hygienists in the study will not be known until the end of the study.

What happens if I say “Yes, I want to be in this research”?
- You will be provided with a link to an electronic survey
- You can answer the questions in this survey on any electronic device
- This survey will take approximately 15 minutes to answer
- There is no time limit on the survey; you may take as much time as needed
- Once you start the survey you can stop at anytime, but answers will not be saved until completed
- Answers will not be saved unless all questions are answered
- Answers will not be used in the study unless all questions on the survey are answered
- The survey will be open until Saturday, August 14th, 2021 and will close at midnight.
- You can take the survey until midnight the last day it is available
What happens if I say "Yes", but I change my mind later?
You can leave the research study at any time and no one will be upset by your decision.

Will it cost me anything to participate in this research study? There will be no cost to you for any of the study activities or procedures.

What happens to the information collected for the research?
We may publish the results of this research. However, we will keep your name and other identifying information confidential.

What will be done with my data when this study is over?
Your data will not be used for any future research after this study is complete. Data will be destroyed after this research is over.

Whom do I contact if I have questions, concerns or feedback about my experience?
This research has been reviewed and approved by an IRB within the Human Research Protections Program (HRPP). To share feedback privately with the HRPP about your research experience, call the Research Participants' Advocate Line at 612-625-1650 (Toll Free: 1-888-224-8635) or go toumn.edu/participants. You are encouraged to contact the HRPP if:

- Your questions, concerns, or complaints are not being answered by the research team.
- You cannot reach the research team.
- You want to talk to someone besides the research team.
- You have questions about your rights as a research participant.
- You want to get information or provide input about this research.

Will I have a chance to provide feedback after the study is over?
The HRPP may ask you to complete a survey that asks about your experience as a research participant. You do not have to complete the survey if you do not want to. If you do choose to complete the survey, your responses will be anonymous.

If you are not asked to complete a survey, but you would like to share feedback, please contact the study team or the HRPP. See the "Investigator Contact Information" of this form for study team contact information and "Whom do I contact if I have questions, concerns or feedback about my experience?" of this form for HRPP contact information.

By agreeing to participate, you are indicating that you are at least 18 years old, have read this document, have had all your questions answered, and voluntarily agree to take part in this research study.

Yes, I have read the informed consent and voluntarily agree to participate.

Appendix F: Survey

Thesis survey

Have you been employed as a Dental Hygienists on March 1, 2020 or anytime after this date?

Yes
No

Demographics

Please answer the following demographic questions.

1. Age:
   a. 18-25
   b. 26-35
   c. 36-45
   d. 46-55
   e. 56 or over

2. Gender identity:
   a. Female
   b. Male
   c. Non-binary
   d. Transgender
   e. Prefer not to disclose

3. Marital status:
   a. Married / Life Partner
   b. Single
   c. Divorced / Widowed
   d. Prefer not to disclose

4. Race/Ethnicity: (check all that apply)
   a. American Indian / Alaskan Native
   b. Asian
   c. Black or African American
   d. Hispanic or Latino
   e. Native Hawaiian or Pacific Islander
   f. White
   g. Other
   h. Prefer not to disclose

5. Which state did you practiced dental hygiene in most of the time during the COVID-19 pandemic (March 1, 2020 to present):
   a. 

6. Total years practicing as a licensed dental hygienist:
   a. 1-5
   b. 6-10
   c. 11-20
   d. 21-30
   e. 31 or more

7. Select the options that best describes the setting in which you practice (may select more than one).
8. Approximately how many coworkers do you regularly work with in a given week?
   a. __________

9. Approximately how many patients have you cared for in a given week since March 1, 2020?
   a. __________

10. Select the option that best describes your dental hygiene employment status on March 1, 2020:
    a. Full time
    b. Part time
    c. Temporary
    d. Not employed

11. Select the option that best describes your current dental hygiene employment status:
    a. Full time
    b. Part time
    c. Temporary
    d. Retired
    e. Not employed

12. Approximately how many of your close friends and/or family members have been diagnosed with COVID-19?
    a. 0
    b. 1-5
    c. 6-10
    d. 11-15
    e. 16-20
    f. More than 20

13. Approximately how many of your fellow coworkers have been diagnosed with COVID-19?
    a. 0
    b. 1-5
    c. 6-10
    d. 11-15
    e. 16-20
    f. More than 20

14. Have you cared for patients who have reported a history of COVID-19?
    a. Yes
    b. No
    c. Not sure

15. Have you been diagnosed with COVID-19?
16. Have you received a COVID-19 vaccine?
   a. Yes
   b. No

   (Branching logic: This question will show when Employment Q1 is "Yes")
   a. Yes
   b. No

   Employment
   Please answer the following questions about your employment as a dental hygienist.

   1. Have you left the profession of dental hygiene since March 1, 2020?
      a. Yes
      b. No

   2. Was your reason for leaving the profession associated with the COVID-19 pandemic?
      (Branching logic: This question will show if Employment Q1 is "Yes")
      a. Yes
      b. No

   3. Do you plan to return to the profession of dental hygiene in the future?
      (Branching logic: This question will show if Employment Q1 is "Yes")
      a. Yes
      b. No

   4. What factors contributed to your decision to leave the profession?
      (Branching logic: This question will show if Employment Q1 is "Yes")
      a.__________

   5. What factors will influence your decision to return to the profession?
      (Branching logic: This question will show if Employment Q3 is "Yes")
      a.__________

   6. Have you reduced your working hours as a dental hygienist during the COVID-19 pandemic?
      a. Yes
      b. No

   7. Have you reduced your work hours due to the risk associated with practicing dental hygiene during the COVID-19 pandemic?
      (Branching logic: This question will show if Employment Q6 is "Yes")
      a. Yes
      b. No

   8. Have you reduced your work hours due to family obligations during the COVID-19 pandemic?
      (Branching logic: This question will show if Employment Q6 is "Yes")
      a. Yes
      b. No

   9. What other factors contributed to your decision to reduce your working hours?
      (Branching logic: This question will show if Employment Q6 is "Yes")
Perceptions
Please respond to the following questions as you reflect back to March 1, 2020, until today and indicate the level to which you agree or disagree with the following questions about your perception of practicing dental hygiene during the COVID-19 pandemic. This section contains 19 questions and is the second to last section.

   1. Strongly disagree
   2. Disagree
   3. Neither agree nor Disagree
   4. Agree
   5. Strongly agree

15. I have considered a different profession other than dental hygiene due to the experience of practicing dental hygiene during the COVID-19 pandemic. (I moved this to under question 14 in the electronic survey)
   1. Strongly disagree
   2. Disagree
   3. Neither agree nor Disagree
   4. Agree
   5. Strongly agree

16. I feel/felt practicing dental hygiene is/was more physically demanding than before the COVID-19 pandemic.
   1. Strongly disagree
   2. Disagree
   3. Neither agree nor Disagree
4. Agree
5. Strongly agree

17. I have considered leaving the profession due to increased **physical demands** of practicing during COVID-19. *(Branching logic: this question will show only when Employment Q1 “I left the profession” is NO)*
   1. Strongly disagree
   2. Disagree
   3. Neither agree nor disagree
   4. Agree
   5. Strongly agree

18. I left the profession due to increased **physical demands** of practicing during COVID-19.
   *(Branching logic: This question will show only when Employment Q1 “I left the profession” is YES)*
   1. Strongly disagree
   2. Disagree
   3. Neither agree nor disagree
   4. Agree
   5. Strongly agree

19. I have considered leaving the profession due to **risk associated** with practicing during COVID-19.
   *(Branching logic: this question will show only when Employment Q1 “I left the profession” is NO)*
   1. Strongly disagree
   2. Disagree
   3. Neither agree nor disagree
   4. Agree
   5. Strongly agree

20. I have considered leaving the profession due to increased **stress** of practicing during COVID-19.
   *(Branching logic: this question will show only when Employment Q1 “I left the profession” is NO)*
   1. Strongly disagree
   2. Disagree
   3. Neither agree nor disagree
   4. Agree
   5. Strongly agree

21. I left the profession due to the **risk associated** with practicing during COVID-19.
   *(Branching logic: this question will show only when Employment Q1 “I left the profession” is YES)*
   1. Strongly disagree
   2. Disagree
   3. Neither agree nor Disagree
   4. Agree
   5. Strongly agree
22. I left the profession due to increased stress of practicing during COVID-19.

(Branching logic: This question will show only when Employment Q1 "I left the profession" is YES)

1. Strongly disagree
2. Disagree
3. Neither agree nor disagree
4. Agree
5. Strongly agree

Coping

Please respond to the following questions as you reflect back to March 1, 2020, until today and indicate the level to which you agree or disagree with the following questions about coping strategies you have used while practicing during the COVID-19 pandemic. This section contains 15 questions and is the last section.
