Why we like SUSY

- Solves the Naturalness Problem
- Gauge coupling unification (GUTs)
- Predicts a light Higgs boson

R-Parity
conservation →

What We Do

- SUSY must be broken, so introduce soft SUSY-breaking parameters and assume high (GUT) scale values for them
- Evolve parameters down to weak scale using RGEs of low energy effective theory (MSSM)
- CMSSM: GUT-scale universality of soft breaking parameters **some other scale?**
 - 5 inputs: m_0 , $m_{1/2}$, A_0 , $\tan(\beta)$, $\text{sign}(\mu)$

GUT-less CMSSM

- Assume unification of soft SUSY-breaking parameters at some $M_{in} < M_{GUT}$
 - Constraints from colliders and cosmology:

$m_h > 114 \text{ GeV}$
 $m_{\chi^\pm} > 104 \text{ GeV}$ } LEP
BR($b \rightarrow s \gamma$) HFAG
BR($B_s \rightarrow \mu^+ \mu^-$) CDF
($g_\mu - 2$)/2 g-2 collab.

$$0.09 \leq \Omega_\chi h^2 \leq 0.12$$

SUSY Dark Matter

- Solve Boltzmann rate equation:

$$\frac{dn_\chi}{dt} = -3Hn_\chi - \langle\sigma v_{rel}\rangle [n_\chi^2 - (n_\chi^{eq})^2]$$

- Special Situations:

- s - channel poles

- $2 m_\chi \approx m_A$

- thresholds

- $2 m_\chi \approx$ final state mass

- Coannihilations

- $m_\chi \approx m_{\text{other sparticle}}$

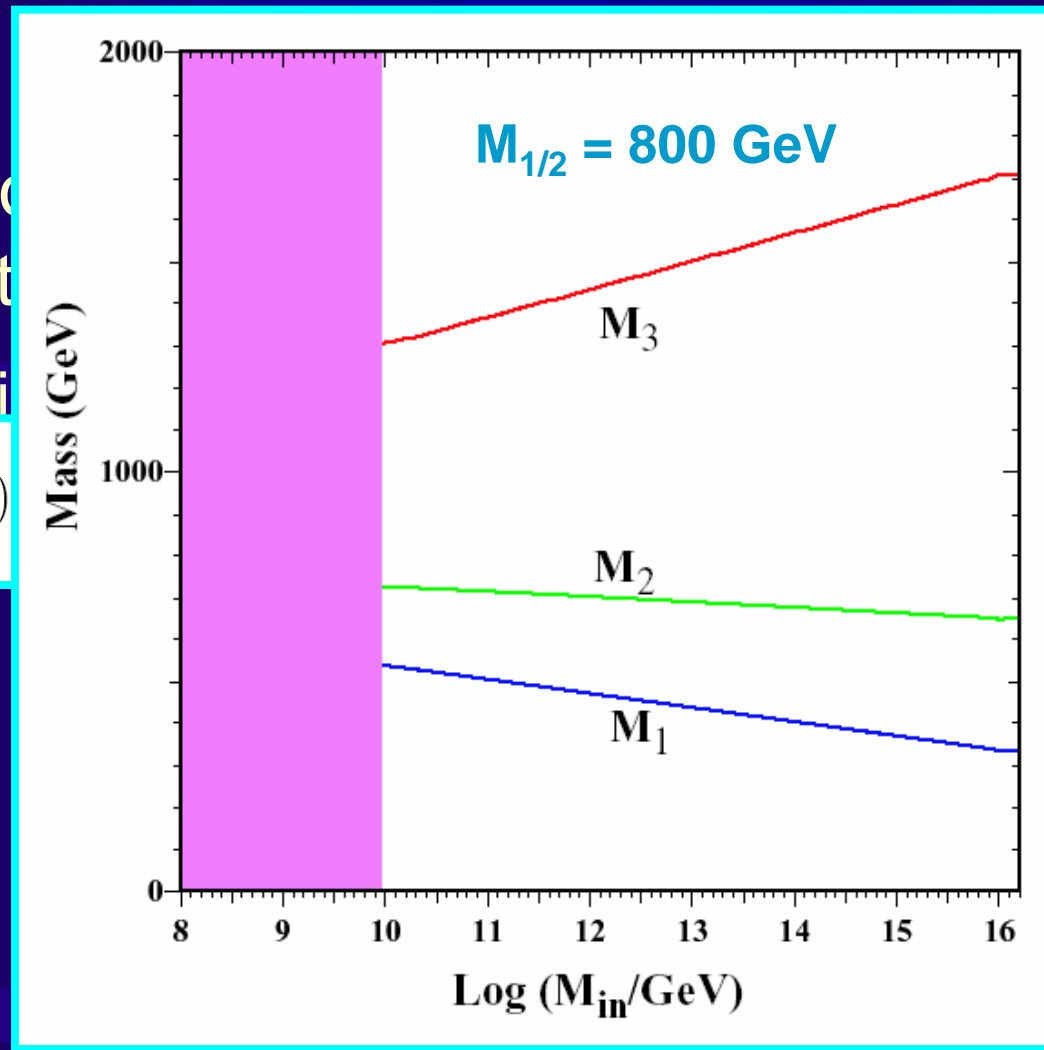

Evolution of the Soft Mass Parameters

- First loop evolution

Gauginos

$$M_a(Q)$$

$$\left(\frac{Q}{M_{in}}\right)^{m_{1/2}}$$

Evolution of the Soft Mass Parameters

- First evolution scale

Evolution of the Soft Mass Parameters

- Higgs mass parameter, μ (tree level):

$$\mu^2 = \frac{m_1^2 - m_2^2 \tan^2 \beta}{\tan^2 \beta - 1} - \frac{M_Z^2}{2}$$

As $M_{in} \rightarrow$ low scale Q , expect low scale scalar masses to be closer to m_0 .

μ^2 becomes generically smaller as M_{in} is lowered.

Mass Evolution with M_{in}

$$m_{1/2} = 800 \text{ GeV}$$

$$m_0 = 1000 \text{ GeV}$$

$$A_0 = 0$$

$$\tan(\beta) = 10$$

$$\mu > 0$$

How do we expect the constraints to evolve?

- m_A decreases logarithmically with M_{in}
 - $BR(b \rightarrow s \gamma)$ and $BR(B_s \rightarrow \mu^+ \mu^-)$ at large $\tan(\beta)$ have important contributions from heavy Higgs exchange. These constraints will become more important as M_{in} is lowered.
- μ decreases as M_{in} is lowered.
 - Expect that the unphysical region where $\mu^2 < 0$ encroaches farther into the plane.
 - When the LSP is bino-like, its mass *increases* as M_{in} is lowered, so the forbidden stau LSP region encroaches into the plane. When the LSP becomes Higgsino-like, its mass *decreases* as M_{in} is lowered, so the stau LSP boundary falls back down.

Neutralinos and Charginos

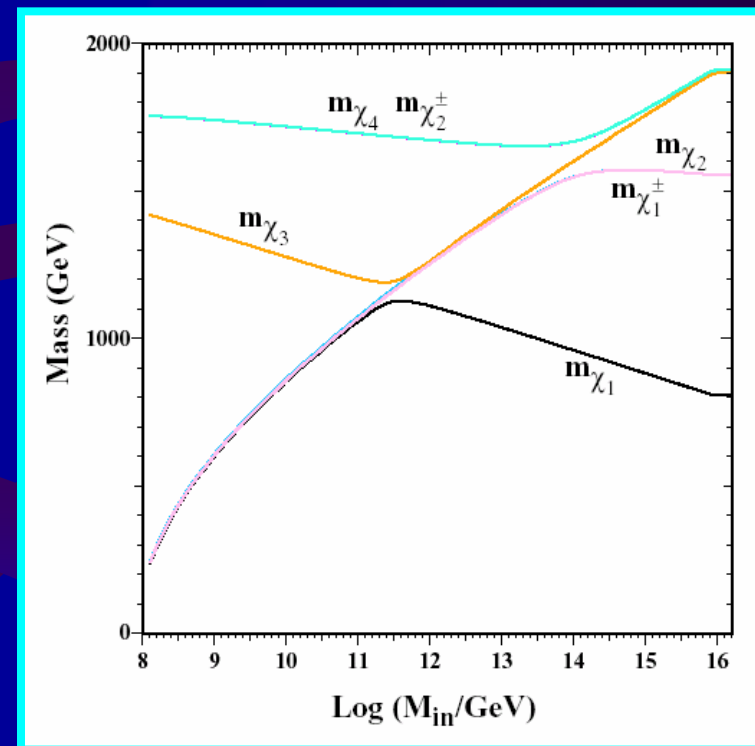

$$m_{1/2} = 1800 \text{ GeV}$$

$$m_0 = 1000 \text{ GeV}$$

$$A_0 = 0$$

$$\tan(\beta) = 10$$

$$\mu > 0$$

Must properly include coannihilations involving all three lightest neutralinos!

Standard CMSSM

Focus Point

$\mu^2 < 0$
(no EWSB)

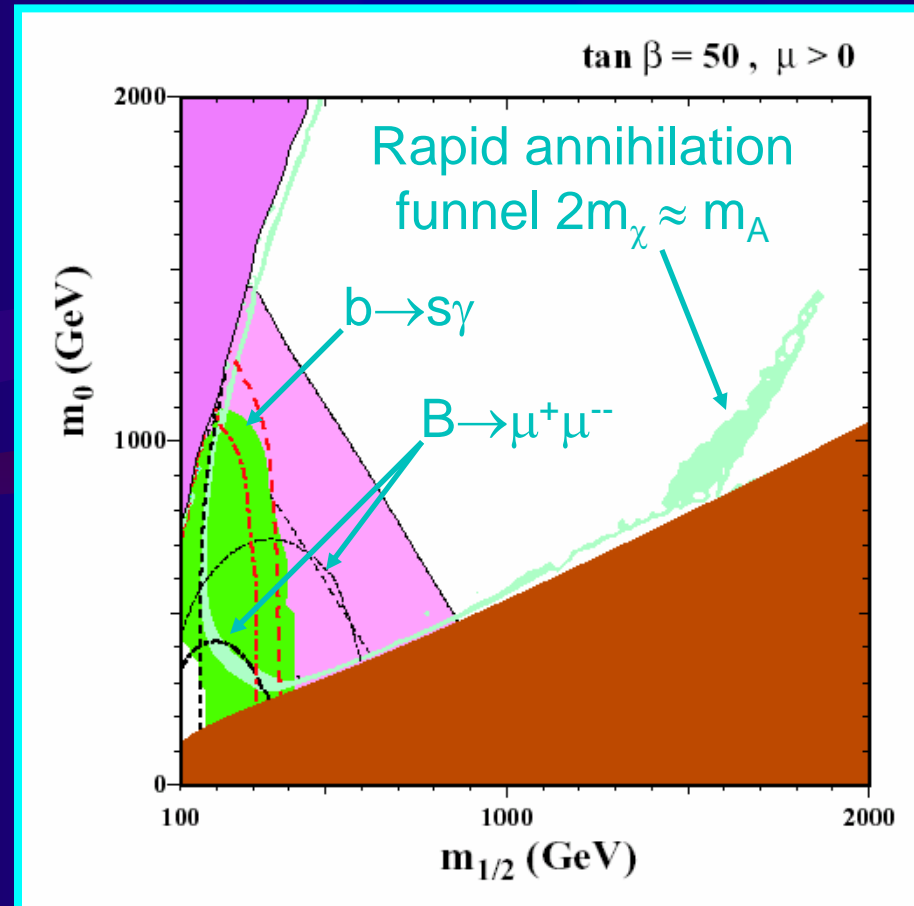

Pearl Sandick, UMN

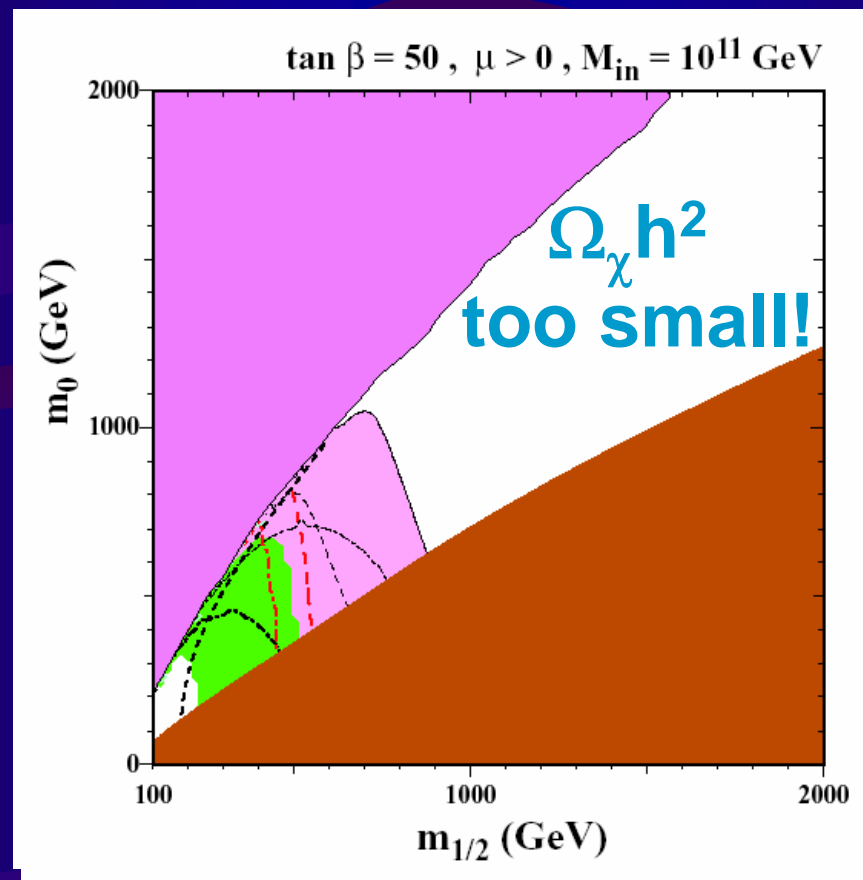

Lowering M_{in} - $\tan(\beta) = 10$

Large $\tan(\beta)$

Lowering M_{in} - $\tan(\beta) = 50$

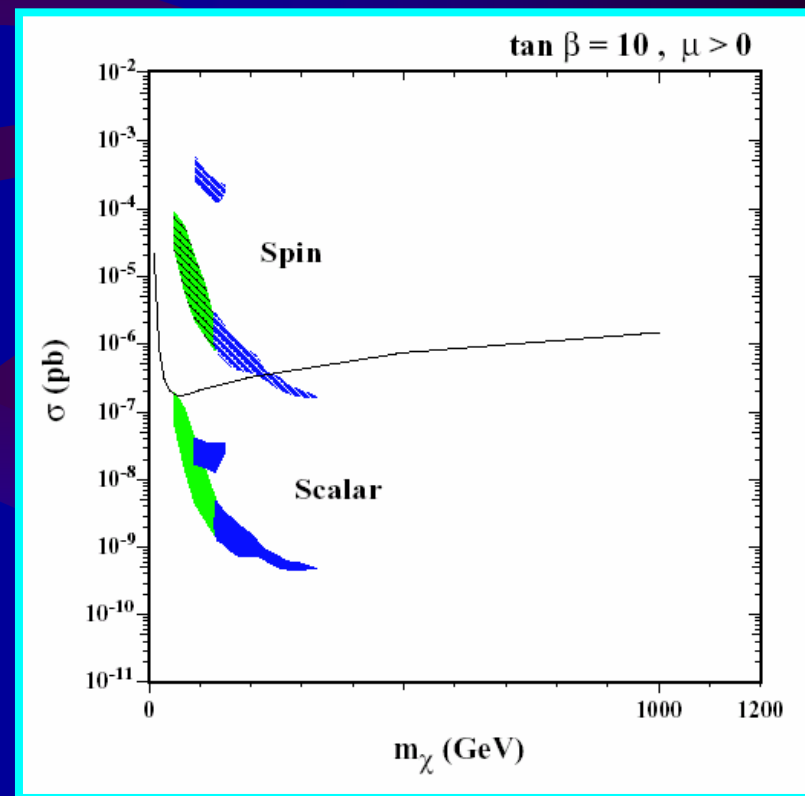

$$A_0 \neq 0$$

- $A_0 > 0 \Rightarrow$ larger weak-scale trilinear couplings, A_i
- Large loop corrections to μ depend on A_i , so μ is generically larger over the plane than when $A_0 = 0$.
- Also see stop-LSP excluded region

Direct Detection: Neutralino-Nucleon Cross Sections

Conclusions

- Intermediate scale unification results in:
 - Rapid annihilation funnel even at low $\tan(\beta)$
 - Merging of funnel and focus point
- Below some critical M_{in} (dependent on $\tan(\beta)$ and other factors), all of nearly all of the $(m_{1/2}, m_0)$ plane is disfavored because the relic density of neutralinos is too low to fully account for the relic density of cold dark matter.
